ON THE DIAGNOSIS AND TREATMENT OF THE SO-CALLED PSORIASIS SYPHILITICA.

By Dr. M'CALL ANDERSON,

LECTURER ON PRACTICE OF MEDICINE IN ANDERSON'S UNIVERSITY, PHYSICIAN TO THE DISPENSARY FOR SKIN DISEASES, ETC., GLASGOW.

THERE seems little reason to doubt that the want of success which so frequently attends the treatment of diseases of the skin is due, not so much to an ignorance of the class of remedies serviceable in the treatment of cutaneous affections generally, as to the use of these remedies in improper cases or stages; or, in other words, to errors of diagnosis.

There can be no doubt that the two greatest difficulties in the diagnosis of skin diseases are, to distinguish a syphilitic affection of the skin from one which is not syphilitic, and to distinguish scabies from an itching skin disease which is independent of the itch-insect, or *vice versâ*. Hence, when scabies occurs in the subject of a syphilitic eruption, the diagnosis may be extremely difficult, as in the following case:—

A gentleman had an eruption on his skin, supposed to be non-syphilitic psoriasis, and treated by his medical attendant by arsenic, but to no purpose. I was accordingly requested by the latter to give him my opinion of the case. It was evident that the eruption was itchy, for a pruriginous eruption was detected, and while psoriasis is sometimes accompanied by much irritation, the situation of the pruriginous eruption, which was most abundant on the front of the forearms, inner aspect of the thighs, and lower portion of the abdomen, led me to suspect scabies. I accordingly searched for and found a female acarus embedded in the extremity of one of the canals which that parasite digs in order to lay its eggs. There could be no doubt, therefore, that the patient was labouring under scabies; but it was evidently not an ordinary case of scabies, for a number of patches covered with silvery scales, such as are not usual in this complaint, were detected. These patches were not, however, on the usual sites of non-syphilitica psoriasis, and they had, besides, a decidedly coppery hue, which led me to make inquiry into the history of the case. I was told that a few months before I saw the patient he had a sore on his penis, followed by enlargement of the glands in the groins, and on examining him I detected a marked tendency to falling of the hair from atrophy of their bulbs, superficial syphilitic ulceration of the throat, and enlargement of the posterior cervical glands; in fact, the usual concomitant symptoms of a secondary syphilitic eruption. An outward treatment was adopted for the cure of the scabies, and a mercurial course for the removal of the psoriasis, and in a short time his skin was completely free from irritation and eruption.

Most of the cutaneous manifestations of syphilis are named from their resemblance to non-syphilitic eruptions, and so it is with regard to the so-called psoriasis syphilitica. Every scaly syphilitic eruption which resembles non-syphilitic psoriasis is termed psoriasis syphilitica. The latter is not usually a primary affection of the skin, but occurs as a second stage of many of the others. Thus, in the second stage of a papular syphilitic eruption (the so-called lichen syphiliticus), desquamation of their summits takes place, and the scales may have a silvery appearance much resembling non-syphilitic psoriasis guttata. This is one of the varieties of syphilitic psoriasis.

Again, in cases of rupia syphilitica, after the crusts due to the desiccation of the pus have fallen off, circular copper patches are left, which are often covered with silvery scales resembling very closely non-syphilitic psoriasis. Here we have another variety of psoriasis syphilitica. A case of this kind was lately exhibited by Dr. Gairdner at a meeting of the Medico-Chirurgical Society of Glasgow, the disease having originally had all the characters of syphilitic rupia, but at the time it was shown having the appearance of psoriasis, and one of the members could not understand how a disease could be rupia at one time, and psoriasis at another, having never taken into account the circumstance that syphilitic psoriasis is, in most instances, merely a second stage of another form of syphilis, and named psoriasis for convenience of description. So much for the relation which syphilitic psoriasis bears to the other cutaneous manifestations of syphilitis.

Now, if it be true, as I hold it to be—that all syphilitic skin affections which resemble non-syphilitic psoriasis constitute the so-called psoriasis syphilitica, it follows, of course, that the disease which is most likely to be mistaken for it is non-syphilitic psoriasis, and further that the diagnosis is sometimes extremely difficult. Of the frequency of such an error, too many illustrations have come under my observation, for not only have I often been consulted by

patients labouring under specific psoriasis, who have had long courses of arsenic on the supposition that the complaint was psoriasis vulgaris, but I have unfortunately, with even greater frequency, seen cases of psoriasis vulgaris, which had been treated by mercury to the extent of profuse salivation, on the supposition that they were syphilitic in their nature.

Such being the case, I offer no apology for appending the following table, which serves to illustrate the salient points of difference between these two affections :—

DIAGNOSIS OF SYPHILITIC FROM NON-SYPHILITIC PSORIASIS.

Syphilitic Psoriasis.	*Non-syphilitic Psoriasis.*
1. Eruption not usually very extensive.	1. Eruption sometimes covers the greater portion of the skin.
2. Usually occurs as a second stage of some other form of syphilitic eruption.	2. The patches assume the characters of psoriasis from the very first.
3. Some of the patches may be moist, or covered with crusts, or even in a state of ulceration.	3. A dry eruption throughout.
4. Patches usually small, and in the shape of round spots or patches, or circles, or segments of circles.	4. Patches often small, and circular, but frequently very large and irregular.
5. Eruption not usually on the elbows and knees ; more on the inner than the outer aspect of limbs. When limited to soles or palms, always syphilitic.	5. Eruption on any part of the body, but *almost* invariably on the elbows or knees also.
6. Eruption in the chronic stage usually *distinctly* coppery in tint.	6. Patches of a dusky-red, or *light* coppery tint.
7. Scales thin ; not so imbricated ; often grayish.	7. Scales thick, imbricated, white, and silvery.
8. Rarely itchy.	8. Sometimes not itchy, occasionally intolerably itchy ; generally slightly so, especially when new patches appearing.
9. May last months, or even a year or more, when no treatment employed.	9. Often of five, ten, fifteen, twenty, or thirty years' duration, or even lasts almost a whole lifetime.
10. Almost always commences after puberty, and usually after twenty.	10. Many cases commence before puberty.
11. Can often be traced to a hard chancre.	11. Can often be traced to hereditary taint.
12. Patient *may* be cachectic, and concomitant symptoms detected ; *e.g.*, roseola syphilitica, lichen syphiliticus, condylomata, sore-throat, alopecia, &c.	12. Patient generally in comparatively good health, with the exception of the eruption.
13. Removed almost invariably by mercury.	13. In the majority of cases removable partially or entirely by arsenic or tar.
14. A relapse not usual after *all trace* of the first eruption has *completely* disappeared.	14. Relapses are the rule, and are often very numerous.

It must always be borne in mind that there is no reason why a patient labouring under syphilis, may not, at the same time, be affected with non-syphilitic psoriasis. But should such cases be observed, and they are not very uncommon, a remembrance of the possibility of such an occurrence should prevent error, especially as it will usually be found that the date of appearance of the non-syphilitic psoriasis does not correspond with the date of appearance of the manifestations of syphilis.

The promulgation of extreme views in medicine, as in everything else, is much to be regretted, and I must confess to having little sympathy with the so-called non-mercurialists, except in so far as they have tended to check the immoderate and indiscriminate use of mercury. For no one who has had much experience of the treatment of the cutaneous manifestations of syphilis can have failed to observe the almost magical rapidity with which they generally yield to it ; indeed, if this remedy is to be withheld, I, for one, know not how we are to combat successfully, that too numerous class of skin affections, dependent directly or indirectly upon the syphilitic taint. It is not, however, to be inferred from this, that every syphilitic skin affection is to be treated in a routine way with mercury. Thus, we must be much more cautious in the use of it when suppuration and ulceration are prominent features of the complaint, for it is a well-established law that syphilitic eruptions are generally of a dry nature in good constitutions, while there is a tendency to suppuration and ulceration in bad ones, or when the health of the patient, no matter from what cause, has been much deteriorated.

Further, it may be remarked, that with the above exception, the constitutional treatment of syphilitic skin disease, depends, not so much upon the appearance which it presents, as upon the general health of the patient, and upon the stage of the disease, iodide of potassium being much more effectual in the later than in the earlier stages of the disease, and mercury being much more frequently indicated in the former, though often of great value in the latter.

In the general treatment of psoriasis syphilitica, if the constitution is bad, the general health must be carefully attended to, cod-liver oil, tonics, such as cinchona and iron, and iodide of potassium,* in full doses, being especially useful. If, on the other hand, the constitution is good, and there is no debility apart from that which is the direct result of the poison in the blood, the patient may safely be put fully under the influence of mercury, the gums being kept *gently* touched for two or three weeks if necessary.

There seems no reason to doubt, however, that in the treatment of the cutaneous manifestations of syphilis, the constitutional is too universally employed to the exclusion of local treatment, which is often sufficient of itself to effect their removal. It is unnecessary to insist on the great value, in this respect, of the mercurial vapour bath, this method of treatment having been so prominently brought under the notice of the profession by Mr. Henry Lee. These baths may be taken every second day, and they possess this advantage over constitutional treatment, that they act directly upon the affected parts, and do not, except in rare cases, give rise to salivation, even when continued for a considerable time. They may, accordingly, be used with advantage in combination with constitutional treatment of a tonic and strengthening character, even in debilitated and strumous subjects.

A more valuable method of treatment even than the mercurial vapour-bath for the removal of the eruption under consideration is an ointment containing calomel, as in the following formula :—

℞ Calomelanos, ʒi.
Glycerini amyli, ʒii.
Unguenti Rumicis, ʒv. ℿ.

Let a little of this be rubbed firmly into the patches night and morning. One of the mercurial ointments of the British Pharmacopœia may be used instead of the above, and often with advantage, as the unguentum hydrargyri ammonati, nitratis, iodidi rubri, &c. When these ointments are used, the patient should, in every case, be warned of the possibility of the absorption of the mercurial, to such an extent as to produce salivation, particularly if the eruption is extensive, and told to show himself at once, should there be any decided indication that the gums are touched.

While anti-syphilitic treatment is being carried out, the patient should, as a rule, avoid stimulants entirely, his diet being simple but nourishing, and after the eruption is completely gone, a course of tonics may be of great service, and a change of air when it can be accomplished.

* E.G. ℞ Ferri et ammoniæ citratis, ʒiii.
Potassii iodidi, ʒi.
Syrupi Zingiberis, ʒii.
Infusi. cascarillæ ad, ʒxxiv. ℿ.
Sig. A tablespoonful in a wineglassful of water thrice daily.

REPORT ON DISINFECTANTS.

By Dr. PROCTER, F.C.S.

(From the Report presented to the St. Andrews Graduates' Association.)

FACTS afford just reasons for concluding that the air is a medium by means of which diseases may be transmitted either by special germs or by the presence of organic matter undergoing putrefactive changes.

All the known phenomena concerned in the production of zymotic disease would point out the causes to be organic germs, diffusive, and in some cases at least, and under certain conditions, capable of being produced. If, then, the presence of organic matter, or the products of its changes, be the essential causes of a certain class of diseases, and if it be true that another class of infectious diseases are communicated by a special organic molecule, are there any means of destroying or arresting the changes in such bodies that their injurious influences may be stayed or prevented? Substances capable of effecting this object are disinfectants, and this they do in one of two ways. 1st. Either by preventing the compound from changing its original composition ; or, 2nd, by rapidly hastening its decay to innocuous material by a process of oxidation. To the former class the term antiseptic is applied, while the latter are known as disinfectants. Practically another class—fixative—may be added, such as Burnett's fluid, &c., which act by entering into combination with the offensive volatile products. Substances capable of destroying bad smells, deodorisers, are often considered synonymous with disinfectants, but this is not the case, for there is no evidence to show that any infectious disease is of necessity associated with odorous matter.

Oxygen, on account of its wide chemical affinity, is the great purifier of nature, and the great natural disinfectant, carried on most energetically by the allotropic form of ozone. When we imitate this wide process by artificial means, the action is complete, as exemplified by combustion, or by chemical agency. As disinfectants, it is to agents coming under the latter head that we have to deal ; their operation is exerted mainly upon the volatile products of decomposition, or at least do not appear to affect the true organic matter until all the former has been destroyed ; thus, a wide distinction exists between their action and antiseptics, which is specially to restrain chemical change in the organised structures.

Nitrous acid and chlorine are both oxidisers, the former by directly, the latter by indirectly, furnishing oxygen. The action of nitrous acid in the destruction of organic matter is very perfect, but its injurious action on the respiratory organs, and some other properties possessed by it, prevent the employment of this acid in inhabited dwellings.

Chlorine is an energetic destroyer of all organic substances from decay, liberating the nitrogen in a gaseous condition, and breaking up into simple forms ammoniacal, sulphuretted, phosphuretted, albuminous, and cyanogen compounds; but, at the same time, exercising its influence rather upon dead than living matter. An experiment of M. Crooke's illustrates this remark, in which he found that cheese mites, in a foul smelling solution, required a large quantity of chlorine to be added, often the solution was inodorus before they died, but when the mites were put in water, with nothing to divert its energy, they were killed by one-fourth less of the chlorine. As a gas it destroys all it attacks, but does not endow that which is left with any power of resisting decomposition. For rapid action in cases of great impurity, chlorine and some of its compounds are most valuable disinfectants, but unless used with care and caution, precisely the same objections exist to its use as to nitrous acid. If there is in an apartment chlorine enough in the air to give a faint smell, it is, in ordinary cases, sufficient to disinfect.

Iodine seems to be as powerful as chlorine, and admits of ready and graduated diffusion through a chamber, for sick rooms it is superior to the latter.

The alkaline permanganates, under the name of Condy's fluid, are substances which have been lately used extensively. They are extremely energetic oxidisers, but practically expensive. Their principal application is in the disinfection of liquid matter or impure water, and this, if of the most offensive character, is immediately deodorised by their agency, and the acquisition of purity shown by the colour, but it is doubtful whether they can be relied upon alone for the perfect removal of living matter.

Antiseptics or Colytics.—That there are a class of substances which have the power of preventing organic substances from undergoing chemical change, either by arresting catalysis or oxidation, or preventing other methods of decomposition, is undoubted, but at the same time it must be admitted that in many cases their precise mode of action is not settled. They disinfect by preservation and seem often to restrain change, as freezing would do ; yet they do not of necessity play the part of deodorisers.

The fumes of sulphur, or rather sulphurous acid, checks effectually the first development of animal and vegetable life, all animal odours and emanations are effectually and immediately destroyed by it.

This value is mainly dependent upon the strong affinity it possesses for oxygen. For disinfecting purposes, sulphurous acid must take a high rank ; it is effectual, economical, permanent, and rapidly applied, but the suffocating odour, coupled with the poisonous properties of the gas, is an effectual bar to its employmen t under all circumstances. Although they do not admitiof similar application, for some purposes these objectons are removed, and the place of the gas supplied by the use of the sulphites, of which the alkaline compounds are soluble. The most putrid fluid will become comparatively innocent, but not inodorous ; when these salts are added to it, perhaps all that is dangerous is removed, and the compound goes on acting until at last sulphuretted hydrogen escapes; therefore, the whole must be removed before this action sets in. The combination of the sulphites of lime and magnesia with carbolic acid by Mr. M'Dougall has produced a disinfectant equal, if not superior, to any hitherto fabricated for those purposes for which a powder or liquid is applicable, such as stable uses, or the disinfection of fœcal or sewage matter.

But, probably, carbolic acid must practically be ranked as the most important of liquid antiseptics. A large number of empyreamatic products possess similar properties. A saturated solution of this acid destroys plants rapidly, in it fishes and leeches die, and their bodies undergo no putrefaction ; it coagulates albumen ; in this liquid flesh shrivels, becomes hard, and remains in this state for years without putrefaction. But for these purposes, and to destroy the lower forms of life, either animal or vegetable, a certain strength is necessary, as, for example, one per cent. retards fermentation, and one in fifty stops it, but one part of carbolic acid in 1000 of water has no effect on the metamorphosis. There is a limit to the preservation ; flesh putrifies in water containing one part of the acid in 500 of water, but is perfectly preserved in one part to sixty of water ; it therefore seems that we may use such graduated amounts as to arrest or destroy lower organic phenomena, or attack the higher animal and vegetable life. The especial cause of its preservative power is unknown. Experiments prove that it neither depends upon the coagulation of albumen nor the retardation of the oxidising action. Again, it destroys all fermentation, but does not stay the conversion of sugar into starch by diastase, in the preparation of oil of bitter almonds. Carbolic acid acts more effectually, if the solution is of moderate strength. Four per cent. is sufficient for most purposes, and it is of the utmost value in all cases where a liquid disinfectant is needed, when the odour is no objection.

The fixative class comprehend the salts of iron, zinc, lead, &c., variously combined with sulphuric acid, nitric acid, chlorine, &c. Their action is limited chiefly to the offensive gases of putrefaction, according to the salt employed, *e.g.*, Burnett's fluid (chloride of zinc) operates

chiefly upon the sulphide of ammonium, while the peroxide of iron exercises a decomposing influence upon both. Whilst they exercise this influence, a large number of other offensive injurious vapours are confined by neither constituent of the salt. Moreover, the substance acted on is not endowed with a disposition to undergo further chemical changes, and having no true antiseptic property, they require frequent renewal. Their use seems to be specially indicated where large masses of putrefying matter have to be deodorised for a limited time, and at a small cost.

The general characters and properties of disinfectants in ordinary use have thus been described, with the exception of charcoal, which has decidedly taken its proper position and sphere of action. It is the consideration of their properties which would lead to the use of the disinfectant to be employed for any special purpose.

In the sick chamber we shall have to act rather upon the evolutions than the sources themselves, and hence we should select one of a diffusive character, and which will operate rapidly, objects fulfilled by those of the oxidising class. Chlorine is here of the highest value, used with care and caution, and in graduated quantities; in some respects, iodine seems to be better adapted, inasmuch as it is more manageable, and the vapour can be produced to any required amount. By the simple exposure of iodine in a plate or saucer, in the majority of cases, sufficient of the metalloid is volatilized to keep the air of the chamber pure. The evolution of ozone by the methods of Dr. Barker or Dr. W. B. Richardson, is very effectual, but not so simple or of so ready application. Mr. Condy diffuses his fluid through the air mixed with the vapour of water, a plan I have not found of equal efficacy to the preceding. In the disinfection of uninhabited places, the peculiar characters of sulphurous acid seem to be particularly applicable. The room should be closed, and quantities of sulphur burnt in several parts, and the process followed by whitewashing. Nitrous acid is very effective, but forming a deliquescent salt with lime, is liable to keep up a damp condition of the walls, and which may foster the germs of disease. To remove infection from bedding or wearing apparel, the application of dry heat at, or a little above, 200° Fah., is perfect and complete. When liquid matter has to be dealt with, the antiseptic or fixative class will usually be selected—the indications for the use of the latter, has been pointed out.

Disinfectants are, in many cases, very important, but they are no substitute for ventilation and cleanliness; in fact, if alone they are relied upon, their employment may be worse than useless, by leading to a confidence which experience of them does not justify.

CASE OF CONVULSIONS DURING LABOUR.

CRANIOTOMY, TERMINATING IN PUERPERAL MANIA: RECOVERY.

By EDWARD W. ADRIEN, M.R.C.S., L.K.Q.C.P.I.

At two o'clock, A.M., on Dec. 2, I was called upon to visit, in her first confinement, Mrs. D——, a national school teacher in this village, aged about 40, and a woman of rather plethoric appearance, although of a delicate constitution. Upon examination I found the os uteri dilated to about the size of a shilling, with the head of the child presenting, covered by the membranes, and everything, to all appearance, quite natural. I gave her a dose of castor oil, ordered the nurse in attendance to administer a purgative enema, satisfied myself that the bladder was empty, and left the room, expecting that it was a mere matter of time, and that everything would go on most favourably without any operative interference. In about an hour the labour pains began to increase in severity, and came on at very regular intervals, accompanied by the gradual dilatation of the os, the medicine having operated, and, having drawn off her urine, she appeared to be going on very favourably for about three hours, until 6 A.M, when, from the severity of the pains, and the labour making so little progress, I was induced to make an examination per rectum, and found that the sacro-coccygeal joint was completely anchylosed and the coccyx quite immovable, thereby materially obstructing the passage of the head; being in hopes, however, from the great strength of the pains, that it would eventually give way, and that the labour would be terminated naturally, I did not think it prudent to interfere, but merely ruptured the membranes, and waited patiently to let nature take its course.

In this way she remained until 10 A.M., when during a pain she was suddenly seized with a paroxysm of convulsions, her body becoming perfectly rigid, face bloated, and of a deeply livid hue; muscles violently convulsed, and a blowing of frothy saliva from the mouth, accompanied by a rattling noise in the throat; pulse slow and very weak. In about five minutes the severity of the attack passed off, and she lay in a semi-comatose condition, with stertorous breathing and a very slow pulse.

Not being provided with instruments, and considering her only chance of recovery was in being delivered as soon as possible, I immediately sent a messenger for my father, who lost no time in coming to my assistance, and who agreed with me, from the nature of the case, not being able to apply a forceps, the head being so high up, and the woman sinking fast, that we should perform craniotomy without delay, rather than allow her to die undelivered, and at the same time afford her the only possible chance of recovery. I accordingly performed the operation in the usual way, and by means of the crotchet, delivered her of a full-sized female child. The coccyx still remained immovable, and caused considerable difficulty in the extraction of the head, even in its compressed state. The placenta came away, I may say, along with the child.

Immediately after delivery, she gradually regained consciousness, took a small quantity of wine and water, and expressed herself very comfortable, and quite free from pain. I ordered a jar of hot water to her feet, mustard sinapisms to the calves of her legs, gave her a bolus composed of calomel gr. vi., pulv-jalapæ gr. x., confect. sennæ q. s., and left.

At about twelve o'clock noon, two hours after delivery, she was seized with another paroxysm, and worked as in the former one, for about the same length of time. I was now very much inclined to bleed from the arm, but owing to the weakness of the pulse, I thought it better to try the effect of local bleeding, so I accordingly applied six leeches to each temple, had her head shaved, applied cold by means of a bladder filled with ice, and a blister to the back of the neck.

In about half-an-hour she regained consciousness, but did not appear so well as before the last attack, and remained in a sort of heavy sleep until two P.M., when she was again suddenly attacked during sleep with a rigor, followed by another paroxysm, in which she worked for about the same length of time as in the former.

From this until the following evening (Dec. 3) at three P.M., the fits came on in rapid succession, scarcely half-an-hour ever intervening. She still continued to swallow some whey or chicken broth, when introduced into the mouth during the intervals, but was not at any time conscious.

I ordered the blister to be dressed with unguentum hydrargyri, drew off her urine every six hours, and gave ten grains of Dover's powder, with three of calomel twice a-day.

Dec. 4th.—Had no return of the fits since 3 P.M. on yesterday, but still remains unconscious; drew off her urine; ordered a purgative enema containing one ounce of spirits of turpentine, and to continue the calomel and Dover's powder.

At 6 P.M., much the same, bowels acted twice since morning, pulse 100, and rather weak; drew off her urine, and, finding the lochia rather scanty, and the parts very dry and inflamed, I ordered her to be well stuped three times during the night, and a large linseed meal poultice to be placed between her thighs.

Dec. 5th.—At my visit this morning, I have been told that she raved a great deal during the night, and was with great difficulty kept covered and in bed. She is still unable to recognise anyone, and I have remarked a yellowness of the conjunctiva that was not perceptible last evening; pulse 120; countenance pale and anxious; tongue covered with a brownish yellow fur; bowels have not been moved since yesterday evening. After drawing off her urine, and ordering the nurse to administer another enema, I thought well from the character of the delirium and her whole appearance, as well as the acceleration of the pulse, to inform her friends of the possibility of puerperal mania setting in, and to warn them against leaving her alone for a minute, or allowing anything to remain in reach, with which she could either inflict injury on herself or on any of her attendants.

I also ordered her a draught of one ounce of the compound decoction of aloes, and three leeches to each temple, the warm fomentations and poultices, with cold to the head to be continued. I determined to avoid as long as possible the use of opium.

6 P.M.—At my visit this evening I found little, if any, improvement since morning. The delirium has evidently increased, and she has become more unmanageable; bowels acted twice after the draught, but the same inability to empty the bladder continues. I now ordered an enema composed of two ounces of mucilage of starch, with half a dram of tincture of opium. A draught, containing ten drops of the tincture, to be repeated in about two hours in case sleep is not produced by the first, and five grain doses of Dover's powder every two hours, to keep up the effects of the opium, and cause a determination to the skin.

6th.—At my visit this morning I found her considerably worse than on yesterday, very violent, and requires to be kept in bed by main force. She slept for about an hour during the night, but did not seem to be in the least improved by it. I now ordered a draught of twenty drops of tincture of opium, with an enema, containing half a drachm, the enema to be repeated in two hours in case the first had not the desired effect. Drew off her urine, and left.

5 P.M.—Went to sleep in about an hour after the administration of the second enema, which was at one o'clock to-day, being now asleep four hours. I did not disturb her to pass the instrument, but desired the nurse to administer another enema in about three hours after she awoke, in case she was still violent, and to continue the cold to the head.

7th, 10 A.M.—Much better; did not awake until seven o'clock last night, having slept, in all, six hours. Pulse 90. Answers questions quite rational. Passed water this morning without the instrument; bowels moved also. Complaining of a slight headache, but with that exception, expresses herself very comfortable.

8th.—From this day to the present, she has progressed most favourably, and with the exception of slight bedsores, which are fast healing, she is now quite convalescent.

I have asked her if she was ever subject to fits, or any of her family, but she says she never knew of any one belonging to her to be so affected, and that she always enjoyed perfect health herself, until the last couple of months, when she caught cold, and her feet and legs became swollen, in which state she remained until about three days ago.

EXTRAORDINARY FEMALE LONGEVITY.—The following illustration of prolonged existence appeared in the obituary of the *Times* a few days since, where the deaths of ten ladies and five gentlemen are recorded, whose united ages amounted to 1282 years, giving an average of 85 years and upwards of 5 months to each; the united ages of the ten ladies amounted to 868 years, showing that they had reached, on an average, the great age of 86 years and more than 9 months; the oldest lady was in her 93rd year, and the youngest in her 81st year. The united ages of the five gentlemen amounted to 414 years, giving an average of 82 years and more than 8 months to each; the oldest had reached 86, and the youngest 80 years.

Hospital Reports.

ST. THOMAS'S HOSPITAL.

TWO CASES OF VERTICAL FRACTURE OF THE LOWER END OF THE FIBULA, WITH UNREMEDIED DISPLACEMENT OF BROKEN PORTION.

Under the care of Mr. SIMON.

HENRY W., æt. 57, a whitesmith, was admitted into accident ward, under Mr. Simon's care, January 23rd, with an obscure fracture of the leg. He had slipped down on the previous evening in the frost, but in what position his foot was twisted he could not explain. He had limped home afterwards with a good deal of pain.

On admission it was found that there was a projecting piece of bone standing up under the skin, between the ends of the tibia and fibula, close to the ankle, its size being about one and a half inches long, by rather more than half an inch wide. The tibia was traceable in its whole length to the inner malleolus, and the fibula in perfect continuity to the outer malleolus, but the latter had evidently lost considerably in breadth. Examining the outer leg, it was found that the anterior edge of the fibula, close to the ankle, was thickened by gouty or rheumatic deposit, and by comparison it seemed most probable that a vertical fracture of the lower end of the fibula had taken place with displacement of the piece of bone, so that its point lay against the skin. The fragment was rather loose, but, nevertheless, could not be replaced by careful manipulation, and the deformity remained. There was some swelling of the ankle-joint from effusion, but this was not enough in itself at first to obscure the diagnosis.

The swelling soon increased, and with it there remained acute tenderness over the displaced fragment, caused chiefly by its pressure against the skin, and doubtless increased by the frequent attempts at manipulation. He was an irritable, cantankerous man, which rendered examination and manipulation a rather difficult and painful task.

On February 23, thirty-one days after admission, he was discharged at his own request, but the deformity was not improved. The piece of bone, however, had united firmly in its new position, but the skin still remained acutely tender over it. The ankle-joint was rather limited in its movements, and he suffered pain of a marked character when he attempted to walk, so that the result of the case was rather unsatisfactory.

Remarks.—This case was one of the large number of accidents which occurred last winter on the night of the 22nd of January, when a hard frost occurred immediately after, and almost with a fall of rain, making all the roads one sheet of ice. The nature of the injury was somewhat doubtful, but the diagnosis was as described—*i.e.*, that it was a vertical fracture of the lower end of the fibula, with displacement. By one of those curious coincidences which occur contrary to all probability, an opportunity offered itself only a few weeks afterwards of verifying the accuracy of the diagnosis, by the post-mortem examination of an apparently exactly similar case, the details of which form the subject of the following notes:—

VERTICAL FRACTURE OF THE LOWER END OF THE FIBULA WITH UNREMEDIED DISPLACEMENT OF BROKEN PORTION: EXAMINATION OF THE PARTS AFTER DEATH.

Wm. D., æt. 55, a painter, was brought into the hospital March 9th, and placed under Mr. Simon's care. He had fallen while walking, but, being drunk at the time, could give no account of the position of his foot at the time of the accident.

The tibia was found to be fractured at the internal malleolus in a direction running downwards and backwards. The fibula was fractured transversely about two inches above the lower end. In addition to these, however, there was a piece of bone projecting beneath the skin between the tibia and fibula. The fibula was diminished in breadth

considerably, for the lower two inches of the bone, and notwithstanding careful efforts at reduction, the deformity remained. It appeared that a vertical fracture of the fibula existed with displacement of the separated portion just as in the case previously reported. The man was too drunk to take notice of what was being done for him, or to give any evidence of pain during the manipulation of the fracture.

He was very noisy and troublesome, and did not sleep during the early part of the night. About midnight, therefore, washe given half a drachm of tincture of opium, which gradually quieted him. He slept well from three A.M. to six A.M., and then woke up and conversed rationally with the other patients near him; about eight A.M. it was noticed that his breathing was heavy and rather laboured, and he soon became comatose and died at eleven A.M., or thirteen hours after admission.

At the post-mortem examination it was found that the nature of the fracture was as follows:—Besides the transverse fracture, there was a piece of the fibula broken off longitudinally, and involving about one-third the breadth of the bones. This was so shaped that the deeper portion of it ran to an angle, and this had become displaced on to the front of the tibia. It was, in fact, a vertical fracture of the fibula, with a twisting round of the broken piece.

In addition to the fracture the other morbid appearances discovered were contraction, and commencing fatty degeneration of the kidneys, fatty liver, and slight congestion of the lungs. The heart was healthy, and its right side was full of decolourised clot as usual.

Remarks.—These two cases are valuable as showing a peculiar form of fracture in the fibula, in neither case reducible. It must be remarked, however, that after careful examination after death, when the surrounding tissues had been dissected away, the bone could be reduced by the following method:—The extreme lower end was firmly pressed, so as to elevate the receding central angle over the edge of the tibia, and as much rotation as possible was given to it. This angle being upon the ledge of tibia direct pressure backwards sent the whole into its original position. Whether this method might have been adopted with success during the life of the patient, or in the first-mentioned case, admits of a certain degree of doubt, but it would be a guide for the method of attempting reduction in similar cases in future.

The sudden death of this man is peculiar, and the cause of it obscure. The chief disease found was a commencing form of renal, and in such cases death does not infrequently happen with unaccountable suddenness.

KING'S COLLEGE HOSPITAL.

Cases under the care of Dr. BEALE, F.R.S.

(From brief Notes by Dr. TONGE.)

CROUP.—Mary A. C., æt. 3½. Admitted September 24, discharged Sept. 24. *Unrelieved.* Previously ill, 3 days, remission on 2nd day, but worse towards evening; stridulous inspiration; very little cough; pulse 160; respiration 40; crepitation at bases of lungs; was removed by mother. *Died* about 2 hours afterwards.

Treatment.—Ipecacuanha emetics. Hot baths.

CYNANCHE TONSILLARIS.—Emma M., æt. 27, probationer; admitted March 21, discharged April 2; in hospital 12 days. *Recovery.* Previously ill, 1 day. Shivering; headache; anorexia; swelling and redness of tonsils.

Treatment.—Liq. ammoniæ acetatis and chloric ether (2 days); then quassia and dilute muriatic acid.

CYNANCHE TONSILLARIS.—Emily S., æt. 14; admitted March 21, discharged April 2; in hospital 12 days. *Recovery.* Previously ill, 7 days. Headache; vomiting; constipation. Pulse 100; tongue thickly furred; slight swelling about parotids.

Treatment.—Castor oil. Grey powder and rhubarb. Sulphate of iron and quassia.

CYNANCHE TONSILLARIS.—Sarah R., æt. 16, servant. Admitted July 11, discharged July 30; in hospital 19 days. *Recovery.* Previously ill 6 days. Headache; loss of appetite; great dysphagia. Pulse 120; velum and tonsils red and swelled; abscess in right tonsil.

Treatment.—Aromatic spts. of ammonia chloric ether, liq. ammoniæ acetatis, and decoction of bark. Iron and glycerine to throat.

CYNANCHE TONSILLARIS.—W. B., æt. 27; gas-fitter; admitted Sept. 19, discharged Oct. 5. In hospital 16 days. *Recovery.* Previously ill two days. Shivering; giddiness; pains in limbs; abscess in left tonsil and right tonsil successively.

Treatment.—Dilute nitro-muriatic acid, chloric ether, and decoction of bark.

CYNANCHE TONSILLARIS.—A. S., æt. 29, nurse; admitted Dec. 19, discharged Dec. 29; in hospital ten days. *Recovery.* Previously ill eight days. Shivering, headache, and loss of appetite; enlargement of right tonsil, then an abscess in left tonsil.

Treatment.—Aromatic spts. of ammonia, and liq. ammon. acetatis; then quinine dilute sulphuric acid, and sp. chloroformi; iron and glycerine to throat.

CYNANCHE TONSILLARIS.—E. S., æt. 25, schoolmistress; admitted June 25, discharged July 5; in hospital ten days. *Very much relieved.* Weak since diphtheria, six months ago. Previously ill six days. Feverishness; scanty white exudation on tonsils; left tonsil enlarged; fauces red.

Treatment.—Dilute nitro-muriatic acid, chloric ether and liquor cinchonæ; pepsine; iron and glycerine to throat.

PAROTITIS.—Esther H., æt. 22; admitted Sept. 30, discharged Nov. 12; in hospital forty-three days. *Very much relieved.* Subacute inflammation of parotid and cervical glands on right side; became chronic.

Treatment.—Chloric ether and liq. ammoniæ acetatis, (fourteen days.) Dilute muriatic acid and liq. cinchonæ, (ten days,) then quinine, sulphate of iron, sulphate of magnesia, and dilute muriatic acid; aperients; cod-liver oil.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

Dr. FLEMING'S Surgical Clinique.

III.—HERNIA AND HYDROCELE—DISTRIBUTION OF TRUSSES.

DR. FLEMING, in continuation of his previous remarks, commented upon the great frequency of hydrocele in connection with hernia, both in the male infant, child, and adult. In the female, amongst the numerous cases of hernia which he witnessed, he had only once met with hydrocele, and that in the adult. It was in the form of "encysted hydrocele of the round ligament." Its characters were well-marked, yet it was mistaken for hernia. The hydrocele was injected with iodine, and a cure was effected, but after a short interval a hernia supervened—an occurrence by no means unfrequent in these cases of vaginal hydrocele, where the disposition of the hydrocele is as if to grow up to the external abdominal ring, and even to enter the inguinal canal. The diagnosis from hernia is most satisfactory in such class of cases; the upper boundary of the hydrocele is distinct; there is no hernial protrusion; no hernial impulse. Such cases, Dr. Fleming stated, he has recorded, and has often met with.

Tap such hydrocele, and almost immediately afterwards a hernia makes its appearance. The practical lesson here taught is to stay the growth of such hydrocele by tapping them early. The formation of a hernia is otherwise absolutely encouraged. The abdominal rings are necessarily approximated; the inguinal canal is almost obliterated; the internal and external rings correspond, and the hydrocele, hitherto acting somewhat like the pad of a truss, by keeping up the bowel, now allows it to protrude. This

form of hydrocele occurs more frequently than is usually imagined, and is often confounded with hernia. The defined outlines limiting the upper part of the tumour, and the concealment of the testicle at the lower, are too obvious features to escape the attention of the clinical student. Should it so happen that this particular form of hydrocele has been far advanced before advice is sought for, Dr. Fleming recommended that the prevention of hernia should be ensured by a light truss, as the anatomical changes present not alone favoured the rapid development of such hernia, but also promoted its rapid increase in size.

Confining his remarks to inguinal and to inguino-scrotal hernia, Dr. Fleming pointed out the admirable lessons taught by studying the casts and drawings of such in the museum of the hospital. Their value was immeasurable, and by carrying them in his mind, the pupil will find from their study, excellent assistants to the recognition, and the diagnosis of the several distinctive characters of those affections. Hydroceles in childhood are very common, both single, and associated with hernia, and this, at the earliest period of infancy. Dr. Fleming specified the several important points to be kept in view in such cases, and remarked on the great frequency of "vaginal hydrocele" at that period of life, in contradistinction to the "encysted" forms as usually noted by authors, which are by no means frequent in the infant or child. This variety of hydrocele, Dr. Fleming remarked, was far less so in the adult. Very nice discrimination and delicate tactile examination were required in their investigation, and when, at the periods for the distribution of trusses, such cases presented, Dr. Fleming stated that he would not neglect their special consideration.

Dr. Fleming next alluded to other forms of hydrocele in connection with hernia, and more particularly with inguinal hernia, such as "hydrocele of the hernial sac," whether "spurious" or otherwise; he had a most instructive case of that class now in hospital, and it shall have a special clinical notice.

MERCER'S HOSPITAL.

FOUR CASES OF LUXATION OF THE THUMB.

By Surgeon MORGAN,

PROFESSOR OF SURGICAL AND DESCRIPTIVE ANATOMY, R.C.S.I.

HEY'S LUXATION OF THE THUMB IN A CHILD SIX MONTHS OLD.

This case was brought to hospital by the mother, who stated that in undressing the child the evening before its thumb got entangled in the shoulder strap of the dress, and got "a twist." She observed the deformity immediately, but as the child did not seem to be much distressed by it, she waited till morning, when on presenting it at the hospital, all the signs of "Hey's luxation of the thumb" were evident. The shortened stumpy appearance; the metacarpal tumour on the palmar aspect, and the phalangeal on the dorsal; all on a lilliputian scale. Mr. Morgan easily effected the reduction by increasing the deformity, and pushing the base of the phalanx forward. A small guttapercha mould was applied for a few days.

HEY'S LUXATION IN A BOY AGED ELEVEN YEARS.

A boy was using his father's plane, a few hours previous to coming to hospital, and having the thumb resting against the end of the plane, when suddenly it was stopped by meeting a nail in the wood, while he was vigorously at work.

All the signs of Hey's luxation were evident, and the boy suffering considerable pain. The reduction was effected by Mr. Morgan in the same way as the former case, by increasing the deformity and using moderate pressure against the phalanx.

HEY'S LUXATION OF FOURTEEN MONTHS' DURATION.

A boy aged twelve presented himself for treatment at dispensary, suffering from Hey's luxation of the left thumb of fourteen months' duration, the result originally of a fall. He complained chiefly of the "ugliness," and that he had not *quite* as good use of it as of the other, owing to its shortness. On examination, all the deformities were as well-marked as in a recent luxation, but the parts had so accommodated themselves that the thumb was almost as useful as the other; bearing out the remark of Sir A. Cooper, that if the dislocation be left unreduced in cases of extreme difficulty, the patient will still have in time a very useful thumb.

A cast was taken, which is in the Hospital Museum.

HEY'S LUXATION, OCCURRING FOR THE THIRD TIME.

A middle aged woman presented herself at dispensary with a Hey's luxation, which had happened her for the third time within a few months. Mr. Morgan reduced the luxation, which offered no difficulty whatever, as the ligaments were manifestly relaxed. A guttapercha mould was fitted to the parts, with directions to have it constantly worn, and a stimulating liniment to be used night and morning.

Society Proceedings.

SURGICAL SOCIETY OF IRELAND.

Dr. ADAMS, President of the College, in the Chair.

(Continuation of Meeting held December 6, 1867.)

PUNCTURED FRACTURE OF THE SKULL FOLLOWED BY TETANUS.

MR. FLEMING said that the morbid specimens and the drawing which accompanied them, now laid before the Society, were illustrative of a case of injury of the head terminating in rather an unusual manner, and which passed lately under his observation, and that of the President in the Richmond Hospital.

The subject of it was a boy 19 or 20 years of age, who had been working in one of those man-holes in the streets of the city, and who, when at work in the lower part of the hole, was accidentally struck by a fellow-workman on the head with a pick-axe.

The blow was given with considerable force, with the intention of removing an elbow at the side of the hole. The unfortunate young man, not stunned at all by the injury, extricated himself and went to an adjoining hospital. There, he had the wound dressed, from which a large quantity of blood had escaped at the time of the accident, and continued to flow for some time afterwards. He then proceeded home, not suffering in the slightest degree, nor in any manner indicative of mischief within the skull. He remained at home a week, when, one night at the end of that time, he was attacked with soreness in the throat, difficulty in deglutition, and considerable stiffness in the muscles of the neck. The next morning he was brought to the Richmond Hospital by the Catholic clergyman connected with it, and when he walked into the hospital, supported by his father, his appearance struck him (Mr. Fleming) as remarkable. He had that position of the head and neck so familiar to those who had witnessed the cases of cerebro-spinal arachnitis, which had latterly been prevalent in Dublin. At the time no mention was made of the injury which the man had received, and at first he thought it a case of that description. However, having learned that he had received an injury of the head, he examined him carefully, and found a small punctured wound situated at the back portion of the head, almost in the middle line and near the upper angle of the occipital bone. The wound was very small, There was not the slightest elevation of the surrounding scalp, and a probe proved that the bone was bare. It was quite evident the symptoms he laboured under were those of tetanus. His intellect was perfect; and he learned from his father and brothers, that throughout the week which had elapsed from the infliction of the injury he had not manifested the slightest disturbance of the brain. The muscles principally engaged were those at the back of the neck, the sterno-mastoid and the abdominal muscles. Opisthotonos was most severe. He had perfect control over his extremities, and continued to

possess it during the whole of his illness. The case, as in most of these cases of traumatic tetanus, was uninfluenced by any treatment adopted. He tried Belladonna, which was administered in large doses, both the extract, by pill and the tincture, by injection. The treatment commenced on the morning of the eighth day after the occurrence of the accident; he saw the patient in the latter part of the evening and not the slightest effect was produced by the medicine, although he had at the time taken six grains of the extract of Belladonna, in addition to twenty drops of the tincture, administered by injection. He then had recourse to Aconite, and ultimately to Nicotine, the latter being administered in the form of pill. He had limited his remarks to those symptoms which were most prominent on the admission of the boy to hospital, and during his stay. The injury was of that class of fracture, which had got the name of punctured fracture of the skull; and it showed a feature generally existing in all fractures of that class—namely, greater injury of the inner than of the outer table of the skull. The other morbid lesions are indicated in the drawing on the table by a young artist, Mr. Burnside, who had but lately commenced pathological painting, and who exhibited such artistic skill as to justify the hope that he might take the place of that true delineator of nature, the late Mr. Connolly. The portion of the bone fractured, was driven in, and impacted in the dura mater of the longitudinal sinus. Many practical questions arose as to the treatment that would have been suited to this case, had it been seen at an earlier period. If the patient had been seen at the time of the occurrence, would they have been justified, in the absence of any indication of cranial mischief, in having recourse to an operation to anticipate the mischief that subsequently arose? Or when the symptoms of tetanus were established, would they have been justified in operating? The question was one of great practical importance. The occurrence of tetanus in connection with injuries of the scalp was quite familiar to most members of the Society, but the occurrence of it in connection with the special class of injury which existed in the present case was comparatively rare.

Mr. RAWDON MACNAMARA said he took a great interest in the use of Belladonna in cases of tetanus in which it occasionally seemed to have no action on the iris, and he therefore wished to know whether in the present case it dilated the pupils.

Mr. FLEMING replied that there was no such effect produced on the pupils.

Dr. R. MCDONNELL said that the last case of tetanus which he met with was in Jervis-street Hospital. Belladonna itself was not given. He objected now-a-days when they had a carefully made preparation, the strength of which they accurately knew, to use one the strength of which they did not know with certainty. It was Atropine which was used in that case. They were able with it to make a solution of a certain strength, and to graduate the doses with the greatest nicety. Whereas, extract of Belladonna, the strength of which, as every practitioner knew, varied at different establishments. In the case to which he referred, the effects of Atropine were as marked as could be, and the pupils were widely dilated. In that case, in the endeavour of sustaining the patient's strength, he transfused blood from his own arm to that of the patient to the amount of ten or twelve ounces.

Mr. TUFNELL asked if any brain substance appeared through the wound?

Mr. FLEMING replied in the negative.

Mr. TUFNELL observed that looking at the osseous case it would give the idea that it was a case of tetanus from irritation, but on looking at the drawing it would appear as if the dura mater were perforated, and that the brain was exposed. On inspecting the bone it would be seen that there was a slight depression of the inner table, just the injury that would produce the tetanus of irritation—the drawing, however, gave him the idea as if the dura mater had been perforated, and that the brain substance passed through the opening.

Mr. RICHARDSON asked was there any contra indication to the administration of mercury in the case? It appeared to him, from the intense injection of the vessels of the brain and the injection of the dura mater, that it might have been useful.

Mr. STAPLETON should be disposed to look on it not as a case of pure tetanus, but rather a case resulting from inflammation of the brain and its membranes.

Dr. DARBY wished to mention a case of a punctured wound in the skull which came under his notice in the year 1832 or 1833, when a resident pupil in the Richmond Hospital. A boy went out on St. Stephen's Day to shoot with the barrel of an old horse pistol, which he tied on a piece of stick. At the first shot the barrel flew up into the air, and then descended on the top of his skull punching a hole in it, like that represented in the drawing exhibited by Mr. Fleming which he thought most creditable to Mr. Burnside. The boy had a small punctured wound very near the central line, and he was taken up insensible. He was brought to hospital, and a depressed fracture of a small portion of the skull was very palpable. The surgeons in attendance thought it better that he should not be trephined, or any effort made to raise the depressed portion of bone. He was treated on the antiphlogistic principles, got tartar emetic, and was ordered to be bled by Mr. Carmichael. On the 14th or 16th day he got tetanus. He ultimately recovered. He had the boy under his observation for six or eight months after the injury occurred to him, and during that time he never lost that peculiar expression of face which tetanus imparts. Peile, Carmichael, McDowell, and our present President, all saw the case, and decided on the mode of treatment to be adopted. His opinion was that, if immediately after the accident, Dr. Fleming's patient had been treated, he might now be alive.

Mr. FLEMING, in reply, said he appealed to the President, who had seen the case, with reference to the remarks of Mr. Stapleton, whether there could be any difference of opinion as to the presence of tetanus in his case. He had seen symptoms like those Mr. Stapleton alluded to, but they were different altogether from those in the present case, the diagnosis of which could not be questioned. With respect to the appearance in the drawing, which Dr. Tufnell seemed to think indicated inflammation of the brain, it was accidentally put in by the artist. Blood had escaped from the longitudinal sinus at the post-mortem examination, and the whole surface was covered with blood, and the artist painted it just as he saw it. The redness in the drawing was not the redness of congestion or inflammation, but of the blood that had escaped.

Review.

ON DISEASES OF THE LUNGS AND AIR-PASSAGES: their Pathology, Physical Diagnosis, Symptoms, and Treatment. By HENRY WILLIAM FULLLER, M.D.Cantab., Fellow of the Royal College of Physicians, London; Physician to St. George's Hospital, &c. Second Edition. London: John Churchill and Sons, New Burlington-street. Pp. 534.

DR. FULLER is well-known to the profession as the author of a sound and practical treatise on rheumatism, rheumatic gout, and sciatica, now in its third edition, and we gladly welcome from the pen of such an experienced and carefully observant physician, a work on the diseases of the lungs. We are not among those who believe it to be impossible in these days of "specialists," for a man to know two things well; on the contrary, when a man has shown himself an able and correct observer of the phenomena of one kind of disease, we may be sure that the same habits of mind and study will serve equally to elucidate matters connected with any other diseased state, provided the opportunities of observation are equally good in both instances.

Part I. of Dr. Fuller's work explains fully the principles of physical diagnosis, and their application to the investigation of the diseases of the lungs. Considerable space is given to a description of the respiratory sounds, and movements in health, and, indeed, of all that is connected with a normal thorax. These matters are the alphabet of auscultation, and must be thoroughly learned by the student before he can decipher the auscultatory language which will reveal morbid states to him.

We cannot too strongly urge upon any one, commencing the study of auscultation, carefully to peruse this first part of Dr. Fuller's book, and, while doing so, to familiarise himself with the varieties of healthy respiration; then, when this is done, we would suggest the out-patient room of a hospital, and very soon the learner will recognize all the deviations from healthy breathing, likely to be pointed out to him by the physician. Too often a student stands, stethoscope in hand, never troubling to auscult, if the physician dismisses a case with "respiration quite normal," but the remark that one has "crackling," another "gurgling," a third, "bronchial breathing," makes him think that now he has a chance to *commence* learning auscultation, and that here are cases not to be missed.

In his description of the phenomena of auscultation, Dr.

Fuller follows the wise plan of regarding each physical sign, not as indicative of a certain disease, but rather as the natural consequence of a certain physical alteration in the tissues, the source and true interpretation of which must be determined by concomitant circumstances. True to this plan, all through the work we find interesting and often elaborate descriptions of the causes inducing certain phenomena of auscultation and percussion. In the chapter on percussion, at page 60, we find notice of the well-known fact that, "a clear, high-pitched sound of a somewhat metallic character, may be elicited over lung tissue more or less solidified, and that an abnormal resonance may be met with in the infra-clavicular regions when the pleural cavity is three parts full of fluid, and the lung is thereby partially compressed."

We must say that we have always held undisturbed the belief that this phenomenon was simply due to air pent up in the lung tissue by surrounding condensation, and it is satisfactory to find Dr. Fuller, at page 66, to be of the same opinion; we only wonder at its being deemed worth while to spend so much space in the preceding pages in disposing of theories which, though coming from some good authorities, seem hardly worth noticing.

In this same chapter on percussion will be found some valuable remarks on the "cracked pot sound," the precautions necessary in detecting it, and its true pathological meaning.

Chapters VI. and VII. are devoted to auscultation and the respiratory sounds; and the two tables of respiration in health and the changes which occur in the sounds of respiration in disease, embody a small practical treatise on auscultation, so admirably is the information condensed and arranged.

We must, however, pass on now to the second part of the book, which treats of the diseases of the respiratory organs.

The first chapter treats of pleurisy, and we are glad to find that Dr. Fuller has some faith in treatment by medicine, and does not leave his patient to struggle through the disease with no other help than a poultice on his side. We read at page 207:

"Mercury combined with opium exercises a markedly beneficial influence. It appears to check the effusion of inflammatory products and also to promote their absorption." While giving small doses of calomel by the mouth, Dr. Fuller applies some mercurial ointment on linen to the affected side, a plan we have tried with advantage, mixing some ext. belladonnæ with the ung. hydrarg. if there be severe pain in the side.

Our own plan is never to push the mercury to salivation, but to endeavour to give enough to arrest the extension of the inflammation. When this has subsided, absorption of effused products will often ensue spontaneously; if it does not, then we find liquor potassæ and iodide of potassium of great service; but while inflammation continues we do not expect to get absorption to take place.

When speaking of the varieties of pneumonia, five in number, Dr. Fuller places first pneumonia due to inflammation of the interlobular cellular tissue of the lung. These cases are met with usually in rheumatic persons, and are apt to be confounded with pleurisy. They are to be distinguished from ordinary pneumonia by the comparative "absence of crepitation, and by the fact that the crepitation which exists is heard during respiration as well as inspiration; and from pleurisy by the rapidity with which strongly-marked tubular breathing ensues, and continues day after day unimpaired in intensity; by the increase of vocal fremitus; and by the increased resonance of the voice."

The tendency of this form of pneumonia appears to be to induce the condition of lung known as "cirrhosis." The fifth variety of pneumonia described by our author is "chronic pneumonia." "This variety of the disease, when unaccompanied by the deposit of tubercle or other adventitious product in the lung, is extremely rare. It is met with in two distinct forms, the one being commonly the sequel of acute pneumonia, the other occurring as a chronic affection without having been preceded by symptoms of the acute disease." "The second variety ought, perhaps, to be described as fibroid degeneration rather than as chronic pneumonia, and should be classed under the head of phthisis, as being more nearly allied to that disease than to simple inflammation of the lungs. The lung is infiltrated by a reddish, solid, material, which, after a time, becomes distinctly fibroid in character, loses its deep red character, and, in many places, assuming a granite-grey tint, causes the lung to become strikingly mottled. These cases, I believe, form a connecting link between chronic inflammatory consolidation and tubercular infiltration"—p. 277. We are glad to see the researches of Dr. Sutton on fibroid degeneration of the lung, are referred to in the note, and we have ourselves seen this condition of lung demonstrated by Dr. Sutton, in the post-mortem room, at Victoria-park Hospital, the appearances being exactly as given in the above description.

Space compels us to pass over the next chapter of Dr. Fuller's book very briefly. We find at page 385, that zinc and belladonna still hold a high place as remedies for whooping-cough. These two remedies judiciously employed (full directions are given for their employment), are capable of reducing the average duration of an uncomplicated attack of whooping-cough to three weeks or a month.

Chapter IV. is the longest in the book, and, with the exception of a few pages on intra-thoracic tumours, the last; it treats of pulmonary consumption, and abounds in matter that is both interesting and instructive.

We strongly support Dr. Fuller in considering the more appropriate title of this disease, to be simply "consumption," "phthisis," or "tuberculosis," terms which do not convey the erroneous impression of the disease being of pulmonary origin.

So far as our experience goes, the less a consumptive person thinks about his lungs the better. Let him think of his stomach, his skin, and the importance of out-door exercise, while he abstains religiously from cough pills and pectoral mixtures, which nauseate the stomach, destroy its tone, and yet, withal, have little or no curative action over the chest symptoms.

With respect to consumption being an hereditary disorder, Dr. Fuller quotes the records of the Brompton Hospital, which show an hereditary tendency in only 24·4 per cent., but he states as his own conviction, "that an hereditary predisposition exercises a far more extended influence than is indicated by the Brompton Hospital report"—p. 400.

This we quite believe, for judging from pretty extensive experience among the out-patients of a chest hospital, our belief is that a very large proportion of the cases of consumption there met with are due to acquired causes, such as poor living, over-work, close hot work-rooms, and so forth, and these cases commonly present no hereditary history of consumption, and improve under a tonic plan of treatment, in a way that is most satisfactory.

We believe if some of the great lung doctors of London would tabulate some hundred or so of their well-to-do private patients, with a view to noting the prevalence of hereditary taint in the system they would deduce a very much higher percentage than 24·4.

Just now, when the contagious nature of consumption is attracting some attention, it is well to see what Dr. Fuller has to say on this point.

At page 478 he alludes to the belief held by the Italians that phthisis is a contagious disease, and then referring to the instances where a wife, after nursing a consumptive husband, herself falls a prey to the malady, he attributes this fact to the long confinement entailed by nursing in a sick room, rather than to any actual contagion in the malady itself, for being a diathetic disease, it is not of a nature to be communicated from one person to another.

This, doubtless, is the right view of this subject, for phthisis is no more likely to be contagious than is gout or rheumatism.

On the matter of climate as a curative means for the consumptive, we find Dr. Fuller thus writing:—"Here I find myself at issue with the opinions of many excellent and learned physicians, and no less so with popular prejudice."

The point of issue seems to be that Dr. Fuller does not regard a residence in a warm climate, "as the best and most effectual prophylactic in threatened consumption." In our humble opinion, Dr. Fuller is quite right, and the learned physicians and popular prejudice are together in the wrong.

"Medical investigations into the geography of phthisis prove that cold is, if anything, preventive of the disease;" and then Dr. Fuller notes how prevalent the disease is in some warm climates, as France, Italy, Malta, and Madeira."*

These matters show that a warm climate is not necessarily preventive and curative for all consumptive people. No doubt there are cases, especially where the larynx is affected by the disease, where the patient cannot breathe a cold air; and these cases must therefore be placed in a warm atmosphere, while others with much exhaustion and relaxation of system, are really killed by living in a hot and relaxing atmosphere.

The classification of climates given at pp. 484-85 is admirable.

Among "Medium climates" suitable for the majority of the consumptive, we find enumerated the west coast of Scotland, Cheltenham, Ventnor, and St. Leonard's.

* See, too, for statistics on this subject, a book on change of air in the treatment of phthisis, by Dr. Thorowgood. 2nd edition.

So far as our experience extends, these are all safe and often highly beneficial climates, and it is very easy for the patient to judge from his sensations at these "intermediate" places whether his future wanderings should lead him to a colder or warmer place.

Before concluding, we would commend the remarks on medicinal treatment to the reader. Dr. Fuller, like all good pathologists, is no believer in specifics; his remedies do not form a long list, but he evidently knows well how to handle them.

A man who recognises the remedial sphere of bichloride of mercury in consumption has not watched disease and the action of remedies in vain, and it is not often that one finds a case of phthisis in its third stage cured so completely as was William Wilby, whose case is given in the foot-note to page 504 of Dr. Fuller's book.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 1, 1868.

1867.

AT the close of the year 1866, we laid before the Profession a full account of our plans for the year that has just ended. How far we have succeeded in realizing the intentions we then expressed, the two volumes of our journal for 1867 bear witness. By our works we must be judged, and to them we are content to appeal as the ground of our hope for a still larger support. As then we asked the reader to contrast the current volume with the one that preceded, so now we believe the two last volumes will bear the same test. Let us, therefore, as before, appeal to our performances as superior to promises. Not that we feel there is no more room for improvement. No one can be more sensible than ourselves of our own shortcomings, and these it is our constant aim to remove. We have the best evidence that it is now the general opinion in professional circles that during the past year we have placed the MEDICAL PRESS AND CIRCULAR on a broader and firmer foundation than it previously occupied. Our opinions now have greater weight and authority, and represent more fully the larger and increasing numbers of our supporters. On any question of interest to the medical world, it cannot be said that both sides have been heard until the MEDICAL PRESS AND CIRCULAR has spoken. To those who have laboured to this end, such success cannot be other than gratifying, and it affords us just the stimulus necessary to support us under many vexations and annoyances, and to renew the work with redoubled energy. Success is to us a call to further labour. The wide sympathy and the many congratulations we have received as to what has been accomplished, only encourage us to pursue the career of independence and honesty which has made our journal a truly representative organ of the liberal and enlightened portion of the profession.

Untrammelled by cliques, unfettered by any school, we can the more justly aspire to be the mouth-piece of all. Our columns have never been closed against one set of views, or one set of men. All here find a platform, and each may break a lance with each in any cause that is of importance to the profession.

More than eight-and-twenty years have elapsed since the MEDICAL PRESS was started. Two years are now completed since the MEDICAL CIRCULAR was purchased by the PRESS and amalgamated with it. In these two years much has been accomplished, but so much more in the latter that we may well confine ourselves to that.

As we look back on 1867, we are reminded that, as in the outer world, it has been a time of great convulsions and changes, so in the smaller world of medicine, it has been a year of unusual excitement. Nature and man have combined to render it a memorable period, distinguished by violent disturbances of the equilibrium of routine. Witness the terrible disasters at sea, earthquakes in the West, cyclones in the East, an eruption of Vesuvius; at home, explosions of mines on a tremendous scale, and scarcely less disastrous explosions caused by crime, and all over the world a general upheaval of political passion, yielding only fruits that are not yet ripe, but the nature of which is to be judged by the feverish waiting for events that prevails in all the countries of Europe. So the world medical has been a reflection of such a year of unquiet. Heated controversies, debates teeming with personalities, abuse of men instead of refutation of principles, strong appeals to passion and prejudice—these and similar things have disfigured the annals of British medicine, and engulphed in the whirlpool of contention, that simple love of truth which should prepossess every member of a profession, the highest model of which was at once the exemplar of all humanity, and the leader who, in the exercise of a Divine mission, "went about doing good."

Yet, out of all fury of contending elements, no doubt good may come, and this hope it is that has often cheered us in our task, and nerved us for our share in the conflict. We know that in every instance our desire has been to range ourselves on the side of right. Our first wish has been to serve conscientiously our profession, and raise it to the position it ought to occupy. Petty factions, large parties, these are nought to us. We owe allegiance to the profession as a whole, and rejoice in the opportunity of serving it as loyally as hitherto. It would be useless to recapitulate our struggles in this cause, and thus stir up again strifes that may slumber. Turn we rather to the practical side, and see what has been accomplished through us.

During the past year we have published clinical lectures, essays or other original communications from most of the leading physicians and surgeons of the day. Our hospital reports have included all the great hospitals of London, as well as those of Dublin and other cities. We have also issued special clinical reports on subjects of interest that we have reason to know have given much satisfaction, and which we propose to continue. Injections into the veins and ununited fractures are topics thus treated which may be mentioned. Under the title "Theories of Cholera," a series of articles of a more critical nature has appeared, in which we have had the assistance of severalable writers. Another great subject com-

menced, and to be continued, is that of "Wine and its Adulterations," on which five articles have already been issued, and these have created interest in unexpected quarters. Matters in relation to pharmacy group themselves naturally round the new edition of the *British Pharmacopœia*, which has been analysed in various ways.

The state of the workhouses and the Poor-law medical service throughout the three kingdoms has been done full justice to in our columns, and we have done all that we could to secure for our Poor-law brethren the speedy redress of their grievances. We may say the same for the Army, Navy, and Indian medical officers, all of which we have had occasion to write about.

The rights of practitioners have been assailed in a manner to demand the utmost exertion. Amongst individuals, we may mention Messrs. Field and Statham, both of whom must have felt grateful for the sympathy we tendered, and which has been echoed by all the profession.

Medico-legal investigations of more public consequence have been closely watched, and commented upon. The value of our comments will be here exemplified by mentioning, that they have not only been reproduced in America, but that translations have been widely circulated in Europe.

The same remark applies to the valuable accounts of the cerebro-spinal epidemic in Dublin, that appeared in our columns, and have since been, we believe, more diffused than any medical productions of the year.

As to the many medical societies our pages are full of their reports. The congress of the medical men in Dublin was fully reported by us, although that society has a journal of its own. The proceedings of the British Association for the Advancement of Science, and the Social Science Association at Dundee and Belfast were sifted for our readers. The new St. Andrews Graduates' Association, which promises to be one of the most vigorous of these bodies, has had its inception and doings more fully chronicled by us than by any journal. Nor have we forgotten the International Medical Congress of Paris, nor any of the smaller and less pretentious, but perhaps, not less useful societies that have moved for the advance of medicine. In this place, may be named the reports of the Gulstonian, Croonian, and Lumleian Lectures, all of them this year so remarkable, and all accurately reported by us.

But the exigencies of our share compel us to stop this recapitulation before it is half completed. Other subjects and other departments have had as much attention as these. The interested reader can refer to his volumes. To our best supporters, we can only repeat our assurance that no effort shall be wanting on our part to maintain and augment the position of our journal, and we trust that they will not only continue their support, but enlist others in the same cause, and so increase our ability to do more.

1868.

Appearing as this number does on the first day of 1868, we can scarcely resist the opportunity it affords us of wishing all our readers the many blessings summed up so curtly in the little phrase so popular to day, "A Happy New Year."

It is thus that we are enabled to salute at once thousands of readers united to us, not only by the bonds of a common profession, but a common effort to work together, each in his sphere, towards a great and good object—that of maintaining and advancing that profession, and encouraging every worthy member of it to pursue his course with such ardour and zeal, that when life shall have passed away, as the year that has just closed, he may enter on the new existence with as much *certainty* as he looks into this new year with *hope*.

For ourselves, we prefer deeds to promises, and shall therefore content ourselves with merely saying, that we are prepared to combat error as earnestly, to promote what we think to be right as fearlessly as any of the conductors of this journal for the last twenty-eight years or more. Petty jealousies will not disturb us; we shall keep aloof from them. The rivalries of hostile cliques will be indifferent to us; we shall ignore both, or reprove both, as seems right to our own conscience. The opposition of irreconcilable doctrines must interest us; we shall criticise and examine them without reference to the authors of them. The rights and wrongs of our brethren, in every sphere, will have our constant consideration. We shall uphold the former, and call for the redress of the latter as loudly and as constantly as ever.

The progress of the science and art of healing in all its branches, and through all its ramifications, will be constantly watched; we hope to furnish our subscribers with all the information they will need. Literature, medical and scientific, English and foreign, cannot be dethroned; we shall review it as copiously as heretofore, perhaps more so. We have long held a front place in this department, and have lately tried to give more space to it. Witness our many translations, our gleanings introduced last year, and the length of some of our analytical and critical notices of books. These we hope to make still more valuable, and thus enable us to hold our place with advancing knowledge as the most critical medical periodical.

This scanty programme will be ample for our most ardent admirers. One word in conclusion to each of them. They can best serve us by supplementing it for us by pointing out to their friends what we have achieved in the past, and thus securing for us new support. We have lately lavished on the journal, time, money, work, and influence. Let each one contribute also his mite—both his practical experience in the form of communications, and his influence by obtaining new subscribers. We shall then be able to carry out more effectually all our designs, and each of our three editions, English, Irish, and Scotch, will occupy a position worthy of the men whose interests it advocates.

THE SULPHUR CURE.

It is seldom that a pamphlet devoted to any medical subject attains a literary success. Messrs. Edmonston and Douglas have, however, had the good fortune last year to issue several editions of two pamphlets about sulphur and its use as a remedial agent. The fifth edition of the first, by Dr. Dewar,* of Kircaldy; and the seventh edition of the second, by Mr. Pairman,† lie before us. Not that we are indebted to the publishers or authors for them in the usual way, for they have not been sent to us, but a good friend connected with a non-medical periodical has kindly furnished us with his copies, and as each bears on the title "with the publisher's compliments" *in type*, we presume

* On the Application of Sulphurous Acid, Gaseous and Liquid, to the Prevention, Limitation, and Cure of Contagious Diseases. By James Dewar, M.D.

† The Great Sulphur Cure brought to the Test. By Robert Pairman.

they have been widely distributed. Yet we know not why they should be kept from medical editors, for although they are rather of the popular kind, and Mr. PAIRMAN'S actually takes the form of a letter to the Minister of Biggar, we see nothing in either to be ashamed of. Dr. DEWAR'S pamphlet was intended to call attention to the value of sulphurous acid either in fumes or in the form of spray, especially in contagious diseases and in some affections of the mucous membrane of the air passages.

It was a production he need not blush to acknowledge, and enforced some points with considerable ability. Yet it made no stir in the world until a copy, by a curious accident, related in a pleasant style, fell into the hands of Mr. PAIRMAN, of Biggar, who straightway began to employ the remedy, and with such success as to make him a most enthusiastic believer in its virtues. Gifted with a facility of writing seldom met with in a "country doctor," as he calls himself, and a power of drawing amusement from the most unexpected sources, our convert immediately commences to proselytise. This new medical gospel, though unfolded at Kircaldy, receives its full development at Biggar, and threatens to envelope the whole art of healing in one purifying and invigorating vapour. So grand a curative agent is in fact announced, that its apostle expresses himself as positively relieved on meeting with one unsuccessful case. Talk of a panacea after that!—who will listen?

But let not the reader conclude that we are speaking of a new quackery. Nothing of the kind. Enthusiasm there is, but of a kind we could wish more general, if it should diffuse over medical literature the lightness and readableness of Mr. PAIRMAN'S pamphlet. We shall perhaps be forgiven the countenance we are thus lending his want of gravity, if we announce that Professor LYON PLAYFAIR and Dr. JOSEPH BELL, as well as other eminent men, have been fairly hooked by the same bait. This "pith without polish," or, as some spoke of the style as "inclined to be jaunty," has, we suspect, contributed much to the spread of the new faith; for, after all, there is not so very much new in the notions so ardently propagated. The striking fact is the extent to which faith in the "sulphur cure" is carried.

As a disinfectant, sulphur fumigation dates from the earliest times. Professor PLAYFAIR, in his letter on the new cure, mentions its employment by Ulysses, but even then it was venerable with age, and used as a matter of course. We should be inclined, at the very least, to date it from—

> "The school of Hermes Trismegistus,
> Who uttered his oracles sublime,
> Before the Olympiads in the dew
> Of the early dawn and dusk of time,
> The reign of dateless old Hephæstus."

And surely to the use of nothing else could we more fitly apply the description of the poet—

> "starting from its fountain head,
> Under the lotus-leaves of Isis,
> From the dead demi-gods of eld,
> Through long unbroken lines of Kings,
> Its course the sacred art has held,
> Unchecked, unchanged by man's devices.
> This art the Arabian Geber taught,
> And in Alembics finely wrought,
> Distilling . . . . discovered
> The secret that so long had hovered
> Upon the misty verge of Truth,
> The Elixir of Perpetual Youth."

Never has drug maintained a more universal sway than sulphur. Externally and internally for the most opposite purposes has it been used by the Profession and by the public. By both, sulphur fumes, sulphur ointment, and brimstone and treacle, are still in every day use. Further, liquid sulphurous acid has been long enough in use by the Profession, so that, after all, we reduce the novelty to the use of spray, which was not employed until the atomizer came into vogue. But we readily admit that their faith in sulphur has carried the writers of the pamphlets before us far ahead of others, and we doubt whether many will follow them, when in their enthusiasm, they would persuade us that the chimneys which evolve sulphurous gas in our manufacturing districts, and the London fogs, which contain it, are the chief preservatives of the health of the dwellers in these localities. If so, by all means let us multiply such chimneys, abolish PALMERSTON'S Smoke Act, and congratulate all cockneys on the blessings of the fogs which so frequently encompass them.

THE PREVENTION OF SYPHILITIC DISEASE.

MR. BERKELEY HILL, the Honorary Secretary of the Association for Promoting the Extension of the Contagious Diseases Act of 1866 to the civil population, has published the results of his investigations into the working of the Act in Chatham and Portsmouth.

It appears that the arrangements for the systematic examination of the women who come within reach of this Act are anything but perfect, and though some good has been effected by it, still the advantages which have accrued are very much less than they might have been under a more stringent system.

In the first place, it is only notorious prostitutes who can be inspected, and a great many women propagate clandestinely the disease without check. Again, the Government only takes cognizance of the existence of open chancres, notwithstanding the Venereal Committee report that secondary syphilis is undoubtedly contagious. Moreover, a woman may have spread the disease far and wide before she is suspected of the taint.

Mr. Hill suggests that the periodical examination of *all* prostitutes is an essential amendment, and believes that it would not evoke as much objection on the part of the women themselves as the singling out of one or two from a number.

The accommodation is stated to be altogether insufficient for the number of cases of disease, insomuch that many women known to be diseased must wait several days for admission. The average stay in hospital for each patient is thirty-six days.

The restriction of the Act and its means of cure to a few towns is found to have the effect of attracting to those places numbers of diseased women from neighbouring localities, and as they often remain in the town for a week before applying for admission, the spread of the disease is much increased, and as these towns are often filled with fresh importations of men, who come in for target practice and other purposes, the disease is carried away by them. Despite all these shortcomings, the working of the Act has been attended with sufficient benefit to afford great promise from an extension of its provisions more widely. Dr. Anderson, Deputy Inspector-General of Melville Hospital, supplied Dr. Hill with the following statistics, to prove its good effect produced on the health of the Marines, by the working of the Act.

The strength of the corps was about 1500. This is borne out by comparing the entries for the third quarter

of 1864 with those of the corresponding quarter of 1867, which were—

1864.	Syphilis .	. 95 cases.	1867.	Syphilis	. 45 cases.
	Gonorrhœa	. 21 „		Gonorrhœa	. 33 „
	Total,	116		Total,	78

Dr. Hill's picture of the vice prevalent in Chatham, Rochester, and Stroud, is almost incredibly awful, and if the sensibilities of the Legislature were not shocked by the unveiling of such fearful corruption, the sore could hardly be longer allowed to spread on unchecked.

Notes on Current Topics.

The Gaelic Society, London.

This institution appears to have resulted from the efforts made at various times by the Highlanders resident in London, to unite for social intercourse, and to keep alive their attachment to the dress, manners, and language of their native country, in the land of the Anglo-Saxon. Such a society was first formed in 1778, and when the law which made it felony to wear the highland dress in England was repealed, it increased both in numbers and importance, and at length became chartered as the "Royal Highland Society." Whether, ultimately, it was dissolved or not does not appear, but, subsequently, another was formed, called the "Society of Universal Goodwill," which, however, soon disappeared. Others followed—one termed the "Gaelic Society" in 1808; two more in 1815, the society of the "Sons of Morven," and the "Club of true Highlanders." These adopted different methods of cherishing their national reminiscences, and met with varied success. The present society seems to be the revival of that which was originated in 1808, devoted to more general and worthy ends. It has a committee of management, a president, a treasurer, and a secretary, who is also librarian. The members hold a general meeting every month at 14, Bedford-row, Holborn, and conduct all their proceedings in the Gaelic language. The society is now in a prosperous state, and well supported, and has done more than any previous one of its kind to preserve their nationality, by bringing Scotchmen into association from time to time for their mutual benefit, and by cheering them with the energetic and suggestive accents of their mother tongue.

The Public Health.

The deaths in London last week again exceeded the average; but this time the number in excess is only 74. Taking the large towns, we find the following numbers express the annual rates of mortality for the week:—For the whole kingdom 28 per 1000 persons living, for London 26, Edinburgh 29, Dublin 29. The rate was—33 in Bristol, 30 in Birmingham, 33 in Liverpool, 35 in Manchester, 31 in Salford, 23 in Sheffield, 23 in Leeds, 31 in Hull, 22 in Newcastle-upon-Tyne, and 28 in Glasgow.

The deaths registered in London during the week were 1561, the average number of deaths for that week being with a correction for increase of population 1487.

778 persons died under 20 years of age, 172 were 20 and under 40, 240 were 40 and under 60, 302 were 60 and under 80, and 69 were 80 years of age and upwards.

Zymotic diseases destroyed the lives of 301 persons, 241 of whom were under 20 years of age. Whooping-cough was the most fatal disease in the zymotic class, and caused the deaths of 56 children; 55 deaths occurred from measles; 48 deaths occurred from scarlatina; 21 deaths from small-pox, 4 from diphtheria, 44 from typhus, and 14 from diarrhœa were registered in the week.

From diseases of the respiratory organs (exclusive of phthisis) 409 persons died; of this number bronchitis carried off 244 persons, pneumonia 111, and asthma 14.

159 persons died from phthisis, 67 from diseases of the heart, and 189 from diseases of the brain and nervous system.

Nitro-Glycerine.

The foolhardiness of keeping large quantities of this dangerous compound, and incurring thereby the risk of fearful explosions, is the more reprehensible, because by the simplest means the agent can be rendered perfectly harmless, and restored to its full efficiency just as easily. It is only necessary to add to the nitro-glycerine a small proportion of alcohol wood naphtha, or methylated spirit, when it loses all its explosive power, and can be in this condition kept for an unlimited period. If at any time it is required for use, the solution needs only to be poured into water, when the nitro-glycerine is precipitated in all its integrity.

A defence of this well-abused explosive has been published by its chief manufacturer. Mr. Nobel succeeds completely in disposing of a number of exaggerated statements that have been circulcated during the late alarm, and he produces a number of stories of the liquid *not* having exploded when it might have been expected to do so. His chief point, however, seems to us to fail. He urges that it is not dangerous in the hands of those who understand it, and estimates that some 50,000 workmen are familiar with its properties. The reply to this is, it will get into the hands of those who do *not* know anything about it, and it is during its passage through them that the protection asked for is needed. The Newcastle explosion also indicates that it is not safe, even in the hands of those who are on their guard, and are to *some extent* acquainted with its nature.

Nitro-glycerine is fluid at ordinary temperatures, but crystallises when exposed to a low degree of heat. With these facts in view, the legislature cannot have the least difficulty in forbidding the accumulation of even small quantities of this dangerous agent.

The New Merchant Shipping Act.

This Act, passed in August last (30th and 31st of Victoria, cap. 124), and to which we have so often alluded, comes into operation this morning, and will apply to any ship which belongs to the United Kingdom, and is absent therefrom at the time when the act comes into operation, when such ship has returned to the United Kingdom. Rules and regulations are to be made by the Board of Trade as to the medical stores, including a supply of lime or lemon juice and other anti-scorbutics. A penalty of £20 may be inflicted for selling medicines of a bad quality. Whenever it is shown that any seaman or apprentice is ill through the neglect of the master or owner in the supply of food, accommodation, medicine, &c., the wages are to be paid by such master or owner, but where a seaman is incapable of performing his duty through his own wilful act or default, the wages to become forfeited. On board British ships a seaman or apprentice is to have a space appropriated for his use on deck of not less than 72 cubic feet and 12 superficial feet. Medical inspectors

are to be appointed at ports, &c. Offences committed by British subjects are to be dealt with by the Courts having the ordinary jurisdiction. The harbour-master at Holyhead may be appointed a justice of the peace, within the limits within which he is empowered to act in harbour matters, and to exercise the jurisdiction of a stipendiary magistrate, notwithstanding he may not be qualified by estate to be a justice of the peace. In a letter to the *Times*, Dr. Domett Stone, dating from the Medical Club, powerfully maintains the view he has already expressed respecting the insufficiency of this Act, and declares it will soon need amending. Dr. Stone would have an "obligatory diet scale," in addition to the rules provided by the Act, and in that alone he believes we possess the means of eradicating scurvy. The revelations that have been made as to the state of merchant seamen are surely sufficient to give force to his arguments.

King's College, London.

We hear that the Rev. Dr. Jelf, who has so long filled the office of Principal at this College, has now resigned. A large number of medical men were educated at King's during his principalship, and remember him with feelings of regard.

The New Clinical Society.

The new Society, the formation of which we announced in a late number, will hold its inaugural meeting under the presidency of Sir Thomas Watson, at the Rooms in Berners-street, on the 10th inst.

Outbreak of Cholera in an Emigrant Ship.

A most violent outbreak of the disease has taken place in the ship "Lord Brougham," which arrived at New York on the 6th of December. The day after the ship left Hamburgh with 383 Germans, the disease broke out, and it raged for forty-six days, as many as 100 persons being sick in the ship at one time, and 73 deaths having occurred. The sufferings of the passengers and crew were dreadful, and the passengers who landed at New York were in a state of the utmost debility.

Medical Graduation in the University of Dublin.

A communication addressed by the Rev. Professor Haughton, medical registrar to Trinity College, to a medical contemporary, contains the following passage :—

"As respects the medical profession, the amalgamation of various denominational colleges under one university would be peculiarly injurious, as it would at once destroy the growing desire expressed by Irish physicians for an education in arts equal to that enjoyed by the candidates for the church and bar. The extent of this desire in Dublin may be estimated by the fact, that out of 797 students of medicine at present in the Dublin schools, 235 are students in arts, and intend to graduate in both arts and medicine in Trinity College."

We are curious to learn how such a statement as the foregoing, put forward by the official medical representative of Trinity College, can be justified, especially as the fulfilment of the prophecy depends on the future of the next four years. We should look forward with the utmost satisfaction to the day when all members of the profession should possess a thorough University education in arts; but we are perfectly well aware that such a consummation is simply Utopian, and we do not see that its fulfilment need necessarily be imperilled by the taking of the Arts degree in another University than Trinity College.

We have endeavoured to show that the estimate of 797 medical students in Dublin is totally unreliable, and we cannot conceive by what facts, or from what line of argument, Professor Haughton justifies the astonishing statement that the 235 students "intend to graduate in both arts and medicine in Trinity College."

The Sanitary Condition of the Troops in Abyssinia.

The following communication, extracted from a letter addressed by a member of the Medical Corps to his father, a well-known Irish provincial Surgeon, will be read with interest and satisfaction :—

"Camp Hadoda, Nov. 12, 1867.

"So far as we can now see, the difficulties to be overcome are not of the insuperable character prophesied by people totally ignorant of the country and military affairs in general.

"We are on an exploring expedition now. Colonel Merewether, Phayne, Wilkins, Munzinger, and I form the party. We left Mulkeeto on the evening of the 4th, and went 55 miles up the Nebbagody torrent to a place 5600 feet above the sea, and about 10 miles north of Senafi. The Nebbagody is not marked on any of the maps, but you can make out our position on Keith Johnston. We were close to Mount Sowera. Between it and Senafi we ascended a hill 7000 feet high, and could see the Abyssinian plateau at the direct distance of about five miles. Senafi is about this distance also, but the bed of the torrent in which the way lies is very winding. Such a jolly climate—max. 77, min. 51—very cold—a glorious stream of water, clear as chrystal, and cold as ice. I had to put on warm clothing, and the Sepoys went about with their "Europe Blankets" around them. For political reasons, we did not go into the enemies country, but ascertained that there was no plateau short of the Abyssinian highlands where troops could be placed—that the road was easily practicable for infantry, and that the only drawback on the route is a want of water, in one part of it being 30 miles from one running stream to another. To-day a party proceeded to a place about half way, to dig wells. If water be found (and the natives assert that they recollect wells to be there years ago) this great difficulty vanishes; otherwise, it will be necessary to have water conveyed in skins. We are off to-morrow up the Hadass to Takonda. The route has already been gone over in greater part, and water found in abundance at distances of from four to eight miles. A few companies of sappers will make the road practicable in a very short time, even for artillery. The transport train is the great difficulty at present. Mules are pouring in on all sides, but it will take a couple of months to lick the motley crew of muleteers into shape, but I have no doubt that this department will be worked well. I know nothing as to the medical arrangements, except that Dr. Currie, one of the best men in our department, is coming as P.M.O. You need not be apprehensive about the sick. Sir Robert Napier is one of the kindest men, and always pays particular attention to that point. So far, we have been all well, hardly a soul sick. One of the 3rd Cavalry died of Bright's disease, and a camp follower of heart disease. A few cases of Filaria (Guiniaworm) have been treated in the hospital of the 10th Native Infantry, of course contracted in India. A little later and the *Times* might have had a gushing article. A few cavalry horses have died, most probably in consequence of the sea voyage. The position now is Mulkeetto, the landing-place and great depôt for stores. A railway will be at once laid down to Korneylo or Gorneylo, twelve miles from the place where there is good water. There will be two good routes, one up to Senafi and the other by the Hadass.

"The 33rd and rest of the Scindi Brigade are to be here immediately, and the plot thickens."

Signing of Certificates.

The Secretaries of each of the recognised medical educational institutions of the United Kingdom, have received from the Secretary of the Royal College of Surgeons of London, a communication with reference to a proposed arrangement, by which all certificates of attendance at hospital practice and lectures may be signed by a single officer, to whom the duty shall be entrusted in each school.

We extract the following clauses from the communication :—

"The attention of the President of this College has been called to the great inconvenience occasioned both to teachers and students, by the multiplicity of signatures now required by this College to be affixed to the certificates of attendance on lectures, hospital practice, &c., of candidates for its diplomas ; and he is consequently desirous of bringing the subject before the Court of Examiners, in order, if possible, to simplify the certificates without in any way vitiating their authenticity and reliable character.

"You will be aware that in some medical schools it is already the practice to require that the accuracy of each certificate should be guaranteed, before it is signed by the teacher, by the initials or signature of the dean, secretary, or other regularly appointed officer of the medical school ; and that it is on the faith of those initials or signature that the certificate is signed by the teacher—a practice which would lead to the conclusion that in those schools the signatures of teachers cannot be regarded otherwise than unnecessary."

We are at a loss to discover what advantage it is anticipated may accrue from this arrangement, which, it appears to us, will serve only to make the existing certificate system even more defective than it is at present. The signature of certificates is surely not a great labour to expect from teachers, and as, in any case, if any discretion at all be exercised by the teacher, a communication must take place in each individual case between him and the officer who signs, we do not see how the present machinery can be simplified, by interposing another official between the teacher and the student. Lightly as the responsibility of certifying to the diligence of a student is at present regarded, it would become a mere farce if the performance of the act were shifted into other hands, and we would rather see the Council of the College taking steps to insure the veracity of these certificates, than going with the tide in the certificate buying system.

The Lord Mayoralty of Dublin.

The civic chair of Dublin is this day occupied by a member of our Profession, Dr. William Carroll, for many years Medical Officer to the Extern Department of the Coombe Lying-in Hospital, and a respected member of the Town Council. Dr. Carroll, we believe, was largely instrumental in securing for the Coombe Hospital the Royal Charter and the grant lately accorded to that institution, and thus obtaining for it an official recognition as an educational establishment.

The Walrus.

This creature, lately the object of so much interest at the Zoological Gardens, Regent's Park, has perished of debility, said to have been brought on by entozoa.

Dr. William Ogle, who has lately been elected Assistant Physician to St. George's Hospital, where he has for some years held the Chair of Physiology, is a candidate for the Professorship of Botany, in the University of Oxford, vacant by the decease of Dr. Daubeny. Mr. Church, who now holds the office of Lee's Reader in Anatomy, is another candidate, and it is said that the Rev. G. Henslow will also come forward.

Mr. J. J. Henley succeeds Dr. Edward Smith as Poor-law Inspector. Dr. Smith is to preside over the Medical Department of the office of the Poor-law Board.

Dr. Henry Lawson, editor of the *Popular Science Review*, is the chief candidate for the appointment of Assistant-Physician to St. Mary's Hospital. Dr. Lawson has been for some years connected with the School, and will probably have the unanimous support of his colleagues.

A number of medical students in London are being sworn in as "special constables." This movement seems to have been taken up with great spirit by all classes—in the first few days more than 30,000 specials having been enrolled.

In consequence of an outbreak of fever at Ferling, the Privy Council have sent Dr. Thorne to report. He has previously been employed in a similar capacity.

The Queen and the Prince of Wales both continue their attentions to the sufferers from the Clerkenwell explosion, in St. Bartholomew's and the Royal Free Hospitals.

THE UNIVERSITY OF ST. ANDREWS, AND ITS MEDICAL GRADUATES.

By Leonard W. Sedgwick, M.D., Hon. Secretary of the St. Andrews Medical Graduates' Association.

(Part of a paper read at the late General Session of the Association.)

The University of St. Andrews from its locality has always been, and must continue to be, in so far as medicine is concerned, an examining, not a directly educating body. Without a large hospital, it could not be a school of physic, and so its doctors of medicine, though in every sense of the word graduates, have, with very few exceptions, never been students of their University.

The University of London has a similar function, and while regulating the mode in which its graduates shall obtain their knowledge, it offers no teaching itself, and it allows the student a wide latitude in his selection of a place of study.

The other universities are directly educational institutions as well as examining bodies.

[Dr. Sedgwick here considered the mode of Government in the other universities, and the position of the medical graduates in them. He then continued as follows] :—

In all these noble institutions then, every doctor of medicine has a voice in the government of his university, and a vote for its representative in Parliament. Nationality is nothing ; if a man holds a degree of M.A. or one above it, keeps his name on the books by the payment of the proper fees, and obeys the laws of his country, he is not deprived of the rights pertaining to his degree on any pretence whatever.

Now let us turn to St. Andrews, to the university, the breath of whose life for years has been its medical graduates, and let us see how it is governed. First there is the general council, which consists of the chancellor and the other members of the university court, from and after their first election, the professors, all masters of arts of the university, doctors of medicine of the university, who have as matriculated students of the university, given regular attendance on classes in any of the faculties in the university during four complete sessions, and of all who, within three years after the passing of the Scottish Universities Act (2nd Aug. 1858), established that as matriculated students, they had attended the university for four complete sessions, or for three complete sessions, in the university, and a fourth at another Scottish University, the attendance for at least two or three sessions having been in the Faculty of Arts. All members of the General Council must be twenty-one years of age, and must have their names registered in a book kept for that purpose by each university. Each member on being first registered must pay a fee of five shillings, and also afterwards two shillings and sixpence yearly on the fifteenth of October for the year ensuing, or a composition fee of one pound. The General Council meets twice a-year ; it elects the Chancellor and one of the Assessors in the University Court, and it is empowered to "Take into consideration all questions effecting the well-being and prosperity of the university, and to make representations from time to time on such questions to the university court, who shall con.

sider the same, and return to the Council their deliverance thereon." Secondly, there is the Senatus Academicus, composed of the two Principals and the Professors of both the Colleges. It has the ordinary superintendence and regulation of the teaching and discipline of the university, and the administration of its property and revenues, subject to the control and review of the University Court.

And lastly, there is the University Court itself. It consists of the rector, the senior principal, an assessor nominated by the chancellor, an assessor nominated by the rector, an assessor elected by the General Council, and an assessor elected by the Senatus Academicus. The University Court is invested with the following powers:—

1st. To review all decisions of the Senatus Academicus, and to be a court of appeal from the Senatus in every case, except as otherwise provided in the Universities' Act.

2nd. To effect improvements in the internal arrangements of the university, after due communication with the Senatus Academicus, and with the sanction of the chancellor, provided that all such proposed improvements shall be submitted to the university council for their consideration.

3rd. To require due attention on the part of the professors, to regulations as to the mode of teaching and other duties imposed on the professors.

4th. To fix and regulate, from time to time, the fees in the several classes.

5th. Upon sufficient cause shown, and after due investigation, to censure a principal or professor, or to suspend him from his office and from the emoluments thereof, in whole or in part, for any period not exceeding one year, or to require him to retire from his office on a retiring allowance, or to deprive him of his office; and during the suspension of any professor, to make due provision for the teaching of his class: provided always that no such sentence of censure, suspension, or deprivation, or requisition on a professor to retire from his office shall have any effect until it has been approved by her Majesty in Council.

6th. To enquire into and control the administration by the Senatus Academicus or principal and professors of any college of the revenue, expenditure, and all the pecuniary concerns of the university and of any college therein, including funds for bursaries and other purposes. And where, we may well ask is the representation of the faculty of medicine here?

The University Court consists of six members, of whom one is a doctor of medicine, but not of St. Andrews; he is an Edinburgh graduate.

The Senatus Academicus consists of fourteen members; three are M.D.'s, but again all belong to Edinburgh.

The General Council consists of 368 members, of whom eleven are M.D.'s, and here is the representation of the medical graduates of St. Andrews; for there is one doctor and one bachelor of medicine of the university on it. But perhaps the graduates in other faculties are so numerous that, after all, this may be a fair proportion. Listen to what the registrar of the university says in a return presented to Parliament last session on the motion of Mr. M'Laren.

"There are at present 368 members of the General Council, a further number of sixty-nine are entitled to become so on payment of their fees, thus making 437." This is the number of all the non-medical graduates of the university. The medical graduates are some 1300, and thus a minority numbering just one quarter of the whole is master of the position. But, it may be urged, the proposed Reform Bill would modify this, inasmuch as all M.D.'s who have passed since 1863 would be added to the General Council. It is true they would, and they amount to forty-six; but what are forty-six out of 1300, and as yet even these are not. So at the present time remains the government of the University of St. Andrews, and so are treated its medical graduates; not as in other universities equal in rights and in privileges to their fellow-graduates, but an outcast class, excluded, unrecognised. Strange contrast this little world to the outer and the greater. In the one every ratepaying householder, gentle and simple, rich and poor, learned and ignorant, alike having his vote for the man who is to speak for him in the great council of the nation; in the other a large and intelligent majority, men highly educated and yet practical, whose daily duties require them ever to be reducing thought into action, the very persons if there be such entitled to self-government, tongue-tied and powerless, without a vote or a voice.

Surely such a state of things should not be allowed to continue. It seems a marvel that it could ever have arisen. But monstrous as is the injustice, it is sure to last unless we betsir ourselves actively, not in a momentary burst of enthusiasm, but with a deep conviction of the need of steady, earnest work; for the power of inertia is great. If I have made this account of the government of the university clear to you, I have, I think, in the very narrative pointed out the root of the present evils. It is our utter want of connection with the university. We pass our examination, pay our fees and are capped, and then we go; Alma Mater knows us no more. With no one to speak for us, no one to care for us, what wonder that our interests are never considered, our rights and privileges never asserted. Scattered over the whole kingdom, with no bond of connection, we were powerless until this association was formed, but now I trust another era has begun for us, and united we shall make ourselves heard and felt. Reform, then, is needed, and it is simple as it is necessary, just as it is desirable. Simple, because we require only to be put upon the General Council of our University; just, because what we ask is only equal rights with our fellow-graduates. If clause XXX. of the Scotch Reform Bill were modified as follows, we should obtain all that we could desire in this matter.

"Besides the persons constituting the General Council of each of the said universities in virtue of the sixth section of the Act twenty-first and twenty-second, Victoria, chapter eighty-three, every person shall be entitled to be a member of any such General council on whom the university has, after examination, conferred the degree of doctor of medicine, or doctor of science, or bachelor of divinity, or bachelor of laws, or bachelor of medicine and master in surgery, and the name of every such person shall be registered in the book kept for that purpose, on payment of the usual annual or other fee."

This is clause XXX as it now stands, omitting simply the paragraph which restricts the privilege to those graduates who have attended in St. Andrews, in the faculty to which the degree conferred belongs, two or more classes qualifying for such a degree. The disfranchising paragraph is short.

We should thus be placed on the general council of the university, and as the previous clause confers the franchise on all members of the General Council, we should obtain at the same time, a voice in the Government of our university, and a vote for its representation in Parliament. The university of St. Andrews has never required, and could not require of the candidates for medical degrees, residence within its walls, as a *sine qua non*, but neither does the university of London, and Edinburgh asks for only one year as a necessity. Is it not then unjust in the highest degree that we, who have complied with all the regulations of the university, and have obtained its degree of M.D., should be deprived of the dearly-prized right of a free tongue and an equal voice, which the medical graduates of all other universities possess?

I need not say more on this point, but there is another matter which, in the interest of the university itself requires revision, and that is the following regulation: "The degree of doctor of medicine may be conferred by the university of St. Andrews on any registered medical practitioner above the age of forty years, whose professional position and experience are such as, in the estimation of the university, to entitle him to that degree, and who shall, on examination, satisfy the medical examiners of the sufficiency of his professional knowledge: provided always, that degrees shall not be conferred under this section to a greater number than ten in any one year."

If it be right to grant ten degrees under these circumstances, what possible reason can there be for refusing to grant fifteen or any other number, if so many candidates offer themselves, and are able to pass the examination. No principle is concerned in this charmed number ten, neither is there any principle concerned in the limitation by numbers at all. Its action, whilst unjust to all candidates beyond the ten who may be allowed to graduate, must be injurious to the university by cutting of its supplies. The framers of the regulation doubtless intended by its means to render it impossible for any unfit person to obtain the degree, at least there is no other conceivable purpose to be effected by it, consistently with an honest wish for the welfare of the university. But speaking with all deference and respect to the distinguished Commissioners, under whose instructions it was framed, I cannot but call it a clumsy and fatal device. For by it the earliest applicants and not the most worthy candidates, will be admitted to the degree, and at no distant period the university must die out by a process of starvation. A far better plan now exists for securing a satisfactory examination, and that is the power of visitation possessed by the medical council. Year by year this will become more of a reality and less of a form, and even now it has

borne good fruit in a very much improved examination, at more than one of the Medical Corporations. It would enhance the worth of the degree, not by limiting the number of candidates, but by enacting a high standard of acquirement. There is a still further consideration to be entertained: assuming that the alteration of the regulations which I have indicated is a desirable one, it is also practicable. There is a general impression abroad that to effect such a change an Act of Parliament is necessary, and this would be beyond our powers. But the matter does not stand thus. On reference to the Scottish Universities Act, which I have quoted so frequently, it will be found that there are no regulations for the granting of degrees there, but that by it, twelve noblemen and gentlemen, with our present Chancellor, His Grace the Duke of Argyll at their head, were appointed Commissioners, and empowered, among other things, to "make rules for the management and ordering of the said universities, the manner and conditions in, and under which students shall be admitted thereto, the course of study and manner of teaching therein, the amount and exaction of fees, the manner of examination with the qualifications, appointment, and number of examiners, and the amount and manner of their remuneration, the granting of degrees, whether in arts, divinity, law, or medicine, and to provide that, in so far as shall be practicable, and in the opinion of the Commissioners conducive to the well-being of the universities, and to the advancement of learning, the course of study, the manner of examination, and the conditions under which degrees are to be conferred, shall be uniform in all the universities of Scotland."

But these Commissioners who, by this authority have drawn up the regulations for the granting of degrees in medicine, which are now in operation, were not a permanent body. The act declares that the "powers hereby conferred on the Commissioners shall be in force until the first day of January, one thousand eight hundred and sixty-two, and it shall be lawful to Her Majesty, by and with the advice of Her Privy Council, to continue the same until the first day of January, one thousand eight hundred and sixty-three, and no longer."

And as they are defunct now, and the University Court is the ruling power in their stead, for what says the Act?—Clause XIX. runs thus:—

"During the subsistence and exercise of the powers of the Commissioners, the powers hereinbefore conferred on the University Courts shall be exercised in subordination to, and so as not to conflict with the powers of the Commissioners. But any of the rules, statutes, and ordinances to be framed and passed by the Commissioners, as hereinbefore provided, may, at any time after the expiration of the powers herein conferred on the Commissioners, be altered or revoked by the University Court of the University to which the same are applicable, but only with the consent, expressed in writing, of the Chancellor thereof, and with the approval of Her Majesty in Council."

The University Court then is the body to whom we must appeal, to it we must carry our grievances, and by it, with the consent of the Chancellor of University and of the Queen in Council, they will surely be remedied. For it cannot be doubted that if we prove the existence of an evil, it will not be long allowed to continue.

But we must not ignore the existence of objections to the possession by the University of any power at all to grant the degree M.D. to any non-resident.

Independently of the long possession of this power by the University, and which, in common justice, should not be withdrawn except for good and sound reasons, it is not difficult, I think, to show that such a power is most desirable and advantageous to the University, the profession, and the public.

The University of St. Andrews has no medical school, no large hospital to attract students, and if it is to grant medical degrees at all, it must be to non-residents; for if medical knowledge is required, a student must go elsewhere to obtain it.

Again, it is most desirable for the medical profession that, guarded by the one safeguard, a stringent examination, any of its members should at any time, if so disposed and competent, be able to obtain the doctorate. It is quite unnecessary that I should instance examples of the need of such an University of St. Andrews, but I cannot refrain from directing your attention to an advertisement in last week's medical journals for an Assistant-Physician to the Consumption Hospital at Brompton—"Candidates must be Members or Fellows of the College of Physicians of London, *and* Doctor, or Bachelor of Medicine of a British University." Suppose a man, after some years of practice, led by inclination or accident, to devote himself chiefly to the study of chest diseases; suppose him (no unnatural idea) wishful to be connected with this special hospital, he can without any residence at any special place, become a candidate for the diploma of the College of Physicians, but unless he is more than forty years of age, and unless fewer than ten men have applied to be examined before him, he cannot during that year obtain the M.D. degree. When the next year comes, the chance may have gone for the hospital appointment. Can there be a more cogent reason for leaving the University doors open to such a man as this, provided he can pass the required examination? You may say that when a man has been some years in practice he will not be at the trouble to "get up" minute Anatomy, Chemistry, Physiology, or the refinements of Medicine and Surgery, and would not be able to pass a sufficiently satisfactory examination if he tried. I do not for a moment believe it. Very many here present are practical refutations of this objection. But even if it were so, the existence of a stringent examination would itself prevent any evil accruing in this way, for if no one of such men could pass, no one would pass. Prevent a man from offering himself because you think he could not satisfy the examiners, and you presumptuously bend facts to your theory. Provide a stringent examination, and the facts take care of themselves, there is no need of a theory. This does not at all touch the question of how best to educate the future medical practitioner. No doubt several years spent in study at the outset of his career, in accordance with the regulations of such a University as that of London, is of all ways of obtaining medical knowledge, for most people the best. But the best for most is not the best for all, and the best cannot always be done. If from a scanty purse or other circumstances, a man has to content himself with the minimum of time for study, and forego the honour of a doctor's degree, because he can live only by the sweat of his brow, is that a reason for shutting him out from it for ever. The whole spirit of modern British legislation and thought is against such a monopoly, such an exclusion. Granted that it is difficult when harassed by the cares and worries of actual practice, with others dearer than one's self to provide for, to keep pace with the scientific progress of the day, and to satisfy the requirements of a University examination; all the more honour is due to the man who successfully accomplishes it, all the more reason to put no unnecessary difficulty in his path.

But this provision for which I am contending is eminently advantageous to the public. It is of all things, for it is most important that every stimulus should be given to the acquirement by the medical practitioner of knowledge beyond the more immediate and necessary contingencies of the day, most important that when circumstances demand it, a rising fame, a more responsible position, a wider sphere of usefulness, the coveted title should be within the reach of every worthy aspirant. Honours are not like old china, valuable in proportion to their rarity.

FATAL MISTAKE.—On Friday week an inquest was held before Mr. W. H. Garrington, borough coroner, at Portsmouth, on the body of a child, four years of age, the daughter of Staff-Commander W. H. Petch, of the Royal Navy. It appeared that the child was unwell and was shown to Mr. G. B. Hill, staff-surgeon on board the Royal yacht Osborne, who advised that a dose of antimonial wine should be administered, and that if sickness did not follow a second dose should be given. Two spoonfuls of the supposed mixture were accordingly administered to the child, who then became drowsy, and Mrs. Petch again summoned Mr. Hill, who examined the contents of the bottle, and found it to contain a solution of morphia. The stomach-pump was then resorted to, but, though every remedy was applied, the child's life could not be saved. It appeared that the morphia had been placed in the bottle which had formerly contained the antimonial wine, but that the label had not been removed, and as the two liquids resembled each other, it was very possible to mistake one for the other. The jury returned a verdict to the effect that the child had been poisoned by mistake.

GUTTA PERCHA FUZE IN GLASGOW.—The discovery of a quantity of gutta percha fuze, near a Glasgow gasometer, has been explained. The article was given to a person residing in the neighbourhood, by a man who had found it in another part of the town. Thinking it to be common gutta percha tubing, he tried to mend a pair of shoes with it, when the flame speedily revealed the presence of gunpowder; the good woman of the house, to prevent mistakes, consigned the whole to the ashpit, where it was found.

REPORT TO THE REGISTRAR-GENERAL ON THE METROPOLITAN WATER SUPPLY.

By Dr. E. FRANKLAND, F.R.S.

ANALYSIS OF THE METROPOLITAN WATERS FOR DECEMBER, 1867.

1 Companies.	2 Date and Place of Collection.	3 Total solid impurity in 100,000 parts.	4 Organic Carbon.	5 Nitrogen as Nitrates and Nitrites.	6 Ammonia.	7 Total Combined Nitrogen.	8 Previous Sewage Contamination (Estimated.)	9 Total Hardness.

For the purpose of comparison, I append also the results yielded by Loch Katrine water, as supplied to Glasgow, and by the water supplied to the towns of Lancaster, Manchester and Leicester, when submitted to the same analytical processes. The numbers in columns 3, 4, 5, 6, 7, 8, and 9, all relate to 100,000 parts of the waters. The table is to be read thus: 100,000 lbs. of Chelsea water collected on 2nd Dec., at the Horse Guards cab-rank contained 29·8 lbs. of solid impurity; the organic matter constituting a portion of this impurity contained ·202 lb. of carbon. This solid impurity also contained ·243 lb. of nitrogen in the form of nitrates and nitrites, besides ·002 lb. of ammonia, whilst the total amount of *combined* nitrogen in every form was ·252 lb. The above quantity of water supplied by the Chelsea Company had been, after its descent to the earth as rain, contaminated with sewage or manure matter equivalent to 2130 lbs. of average filtered London sewage.

By gradual oxidation, partly in the pores of the soil, partly in the Thames or its tributaries, and partly in the reservoirs, filters, and conduits of the Company, this sewage contamination had been entirely converted into comparatively innocuous inorganic compounds before its delivery to consumers. Finally, 100,000 lbs. of the Chelsea Company's water contained 21·7 lbs. of carbonate of lime, or an equivalent quantity of other soap-destroying ingredients.

The waters delivered by the Southwark and Grand Junction Companies, were turbid when drawn from the mains, the remaining waters were transparent. The results of the analysis of the Kent Company's waters, collected this month, at Bromley, shew that it is of an entirely different character from that delivered by the same company at Deptford. Not only is the previous sewage contamination of the Bromley water very high, but the presence of a large amount of ammonia, shows the contamination to have occurred very shortly before the water was delivered to consumers. The use of this water for domestic purposes is very undesirable.

SIMPLE FRACTURE OF THE FEMUR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In a recent case of simple fracture of the femur through lower third of shaft, the patient being an old man, and a difficulty being found to get a suitable bandage for the perineum, I found the following plan successful. A piece of galvanised India-rubber tubing, about six-eighths of an inch in diameter, and sixteen inches long, was threaded by a common calico bandage, the ends of which were drawn through the necessary distance at each mouth of the piping. This I applied in the usual way, and it was borne well, being at once soft, waterproof, elastic and clean. Moreover, the same piece of tubing would last for many cases.—Yours, &c.,

Tetsworth. J. C.

PROFESSIONAL ETIQUETTE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Knowing the pages of your valuable journal ever to be open to defend the interests of the profession, I wish, through its columns, to ask how far professional etiquette goes, and in what relation the specialist stands with the hospital physician or surgeon.

Now, sir, living as I do in the second city in Great Britain, with its men occupying the first position as specialists in the profession of which I have the honour to be one, is it correct for the pure physician of medical celebrity, or the surgeon to one of the largest metropolitan hospitals, to undertake special operations in dental surgery (in their own private houses), which have, heretofore, fallen to the lot of those men who are specialists for that purpose.—I am, sir, yours obediently,

RHIZODONTRIPY.

The etiquette of the profession certainly fixes a limit to the prosecution of special branches by general surgeons. There is a tacit agreement on the part of specialists, that they will keep to their own business, and not practice in competition with general surgeons, and the compact ought in all reason to be observed on both sides with equal strictness.—ED. M. P. & C.

CLINICAL LECTURE ON A CASE OF EPILEPTIC HEMIPLEGIA.

By C. HANDFIELD JONES, M.B., Cantab., F.R.S.,

PHYSICIAN TO ST. MARY'S HOSPITAL.

It is generally worth our while to contemplate closely the features of any case of disease when they are strongly marked, and capable of leaving a definite impression on our minds. We should endeavour to attain to some reasonable account of their origin, to trace their mutual relations, and to compare them with other phenomena of different character occurring under like circumstances. By so doing, we can scarcely fail to gain a better knowledge of the whole pathology of the disease. I invite you to consider with me a case of manifestly epileptic character, having a sequela which is somewhat rare, and contrasts strongly with others met with in the same malady.

J. S., æt. 27, admitted August 3rd, 1867, was taken ill July 30th, when he had two fits. These (I believe) were the first he ever had. When attacked he was out of doors in the grounds of Colney-hatch Lunatic Asylum in charge of patients. The fit lasted from ten to fifteen minutes; there was an interval between the two of about one hour. Three hours later he had a third. He remembers being attacked with giddiness, as well as some circumstances which happened shortly after the attack commenced, but from that time he remained quite unconscious until he found himself at home. Since the fits he has remained in a stuporous state, and hemiplegic on the left side. Motor power in the affected limbs is entirely lost, but sensory appears perfect. No strabismus. Pupils large and sluggish. No distortion of face. Tongue put out straight. Answers questions rationally. Pulse weak, 108. Bowels have been much relaxed. Potassii bromidi gr. x. + M. camp. ℥i. *ter die.*

5th.—State same. No fits. Ammon. carb. gr. iv. + infusi valerian, ℥i. *ter die.*

6th.—The muscles of the arm contract pretty briskly with the interrupted current, those of the leg are not quite so lively. He passes all his evacuations in bed. His countenance is deficient in intellectual expression, and gives one the idea of a man who was tainted with insanity. Adde mist. pot. iod. gr. iiss. ad. ℥i. He can move his fingers a little, can flex and extend them.

9th.—Can move the hand and arm better; can open and shut the fingers, and raise his hand to his head; the leg is quite motionless to the will, but moves reflexly when the sole is tickled. Does not soil his bed so much. Not much appetite.

The urine on 10th was found very pale, sp. gr. 1014, turbid with phosphates, of which it deposits a copious sediment, consisting of prisms and amorphous granules, dissolved by nitric acid. Pt. c. mist. addendo, tr. cinch. ℥i. + tr. Valerian ℥i. ad. ℥i.

12th.—Can move the arm about pretty extensively, but the leg is quite motionless unless the sole is tickled. He says, however, that he can move the leg sometimes a little. Tongue too red. Ord. diet—porter.

14th.—Leg still motionless; arm can be moved well, but feels stiff from shoulder to elbow. Urine still passed in bed. No rigidity of arm. Pulse 75, very weak, open. Strychniæ gr. 1-20th + tr. ferri muriatis ℥ xv. + spt. otth. chlor. ℥ x. + aq. ℥i. *ter die.*

17th.—Leg still motionless, except to tickling. More control over sphincters. He feels very weak. Port 6 oz.

21st.—Can flex the leg at the knee pretty well, but not abduct it nor extend it well; cannot quite stand yet. Urine weakly, acid; does not deposit phosphates.

24th.—Can move his leg better. Takes and enjoys his food and wine; pulse very soft and toneless; heart's sounds quite normal; urine deposits phosphates again copiously, is alkaline; paper blued by it becomes red again after exposure to the air; urine effervesces with nitric acid; contains no mucus or but very little; after the phosphates are dissolved there remains only a little opacity.

28th.—Is improving; can stand and walk with a little help. Urine in same state; that passed the other day deposits no uric acid; after being boiled with nitric acid, it becomes of a dark-red colour, and deposits pigment. Camphoræ gr. i. + opii gr. 1-3rd in pil. *ter die.*

31st.—Urine still deposits phosphates copiously; pulse very weak. He can walk now quite well—only halts a little on the left leg. Amount of urine in twenty-four hours, 61 oz.; sp. gr. 1017. The urine effervesces most copiously with strong nitric acid; contains 7·8 grains urea per ℥i. according to one analysis made by Mr. Blades, the ammonia being previously separated; one which I made some hours before gave 11 grains per oz., the ammonia not being driven off,

but neutralized with nitric acid. Taking the lower estimate, the total urea for twenty-four hours—475 grains, exclusive of that which had been decomposed in the production of ammonia. Strychniæ gr. 1-16th + ferri et quinæ citratis gr. viij. + acidi citrici gr. iij. + aq. ℥i. *ter die.*

Sept. 5th.—Urine freshly passed is of sp. gr. 1018, quite clear and bright, acid. Is getting quite well.

14th.—Is doing quite well. Urine 68 oz., total urea = 314 grains; weight on 7th = 111 lbs, and total urea 392 grains.

On Sept. 19th he left the hospital quite well, and came to show himself again on 28th, in very good case.

The prominent phenomena in this case, were the epileptic attack and the paralysis. Had these events been noted in connection with each other for the first time, there might have been a doubt in our minds whether they were really causatively related, or only accidentally concurrent. But quite a sufficient number of instances have now been observed and recorded, especially by Dr. Todd, to make it quite certain that temporary paralysis is a not unfrequent result or accompaniment of the epileptic attack. In most instances, the paralysis follows the fit, but sometimes it precedes. Dr. Todd refers to two instances of the kind, and I have recorded one also in my late work. The exact cause of the paralysis is difficult to determine ; one thing seems to me tolerably certain, that it does not depend on any macroscopic structural lesion, such as extravasation of blood, softening, embolism of arteries. Were it otherwise, the paralysis would not subside and disappear so completely and rapidly as it often does, not lasting perhaps more than a day or two. Does it depend on spasm of the arteries supplying the motor-nerve centres of the paralysed limbs ? This is a mere assumption, and though it might be considered a probable one, if there were co-existing pallor of the face, retina and choroid, I doubt very much whether in the absence of signs of these states, we can consider it a possibility. During the convulsive attack, when unconsciousness is complete, the hemispheres and their basal ganglia may sometimes be deprived of blood, but when the intellectual centres have regained their power, and, therefore, of course, their blood supply, we have strong reasons, it seems to me, for doubting that anæmia is the cause of the palsy of the adjacent motor centres. Moreover, it is, I think, quite a matter of certainty that the most complete unconsciousness, *i.e.*, torpor or paralysis of the hemispheres, may continue long after all arterial spasm, which may have existed at the commencement, has perfectly ceased, and when the exterior of the head, at any rate, is in a marked state of hyperæmia. If then, their centres may remain paralysed for a varying time after their circulation is restored, why may not the motor centres also ? When we consider, further, how cholera patients, when completely pulseless, are able to walk about, and perform mental actions, we cannot regard mere anæmia (local) the result of spasm, which would scarcely effect complete obstruction, as the sole sufficient cause of a functional paralysis. Hyperæmia is pretty sure to be invoked by some as the cause, but I quite agree with Dr. Todd in rejecting this condition, as affording any adequate explanation of the occurrences. The results of long-continued, or intense hyperæmia in a part, viz.—effusion of blood or serum, might give rise to paralysis, but not a mere transitory hyperæmia ; nor would the paralysis so produced be of brief duration. Moreover, the state of our patient, and especially the kind of treatment which we found serviceable, is quite opposed to this view. For my own part, I accept the opinion expressed by Dr. Todd, as coming nearest the truth. He says, v. Clin. Lect., p. 295, " that the exciting cause of the disturbance which constitutes the epileptic paroxysm, leaves behind it a more or less exhausted state of brain. This state of exhaustion is very apt to continue, as one of weakened nutrition, in which the tissue is more or less in the condition of white softening. If the parts involved in this be the convolutions, mental power, memory, perception suffer ; if deeper parts, as the deeper parts of the white matter of the hemisphere, and the corpora striata and optic thalami, then we have hemiplegic paralysis." The only point in which I am inclined to differ somewhat from Dr. Todd, is the occurrence of anything like white softening in the affected nerve tissue. To me the morbid condition is more like that which prevails during profound sleep, and like this in the majority of cases tends to pass away until it is reproduced by fresh disorder. It is just the same condition that is produced by inhibitory irritation of various kinds, nitœa, a blast of cold, a diseased tooth ; or which ensues in chorea, influenza, and often the exanthemata. It is essentially a state of exhaustion, but not, I believe, of discoverable organic alteration.

We cannot doubt that the efficient causes of disease remaining the same, the resulting phenomena vary greatly according to the vulnerability and other qualities of the several organs on which they act. This is strikingly apparent in certain cases of the exanthemata, where one individual has but a single part affected, the others remaining unchanged by that miasm, which, in most of his fellows, occasions grave, general disorder. So also in renal degeneration, the peculiarities of the tissues in different individuals determine very much the secondary disorders which ensue ; one person having convulsions, another dropsy, another pericarditis, a fourth pleurisy. On this ground, I conclude that the paralysis is an event of the same kind as the coma or stupor, which so commonly succeeds an epileptic paroxysm, and that it occurs wherever owing to original or acquired weakness the motor centres are more vulnerable, or at least as much so as the hemispheres are. That the palsy, when it occurs, should last longer than the coma generally does, need not appear to you surprising, since we repeatedly meet with instances in which motor power is much more slowly regained than sensory, or intellectual. In our patient, however, the stupor continued for an unusually long time, his mental faculties were evidently dulled, and to this, I believe, rather than to paralysis of the sphincters, we must ascribe the circumstance that he passed for several days after his admission all his evacuations in bed. The expression of his countenance, in fact, was that of a semi-demented person. That the sphincters themselves were not paralysed is rendered further probable by the readiness with which reflex movements were induced by tickling the soles of the feet, which showed that the lower part of the spinal cord was sound.

The condition of the urine was very noteworthy, and is conclusive, I think, as to the great depression of the nervous, and other powers of the system. The urea underwent, as it appears, spontaneous decomposition, there being only a very small quantity of mucoid substance present in the urine, certainly much less than is present sometimes when no such breaking up of this constituent occurs. Without going beyond the limits of direct observation, it may be stated, I believe, as a fact, that in various morbid states, of which failure of vital power is one of the most prominent features, the excreta are found to decompose with unusual readiness. This has been ably dwelt on by Dr. Inman. That the carbonate of ammonia in the urine was not derived from that which was administered medicinally needs hardly be said, as the drug is continually given without any such result ensuing. Moreover, this state of the urine continued several days after the ammonia had been omitted. Regarding then this (apparently) spontaneous decomposition of the urea as a sure and clear indication of general prostration, I gave strychnia with iron, and port wine, and there can be no doubt, I think, that these means materially promoted the recovery. Simultaneously with the restoration of nerve-power, the urine became quite natural, and what is especially worthy of attention the total urea amount of 24 hours diminished considerably. It is not possible to state precisely the difference in figures, because, as the ammonia was not estimated, we cannot tell how much urea underwent decomposition, and so escaped analysis on the first occasion. It is certain, however, that the amount excreted during full convalescence, with better

appetite and digestion, was less than that which was passed during the period of great prostration by more than 161 grains. This is quite analogous to what is observed in low fever, when the excretion of urea and uric acid during the height of the fever may be more than double of that which occurs during convalescence. Prostration of nerve power is a prime element in fever, and so it was in our patient, and to this prostration I am disposed to refer the increased bodily waste in both cases. The urea amount during the period of convalescence was about in normal proportion to the bodily weight—*i.e.*, about 3 or 3·5 grains per 1lb. Before this it must have been considerably in excess. I am rather disposed to attribute the supervention of the disorder to the patient's occupation. It is not doubtful that attendance on epileptic persons may induce the malady in those who are predisposed. Whether this were the chief cause of the attack or not, I am sure that I have done right in counselling him strongly to seek for other employment. The various morbid manifestations which occur in connection with epilepsy are manifold, and you must be prepared to meet with this foe not unfrequently in a more or less disguised form. As sequelæ of the complete paroxysm, we may have the following different pathological states :—(1). Coma (palsy or torpor of the hemispheres). (2). Mania or violent delirium (hyperæsthesia of the hemispheres). (3). Hemiplegia (palsy of motor centres). As instances of petitmal, or of partial epilepsy, we may have—(1). Brief, sometimes momentary, unconsciousness (palsy of hemispheres). (2). Acts of sudden unaccountable violence, or obscurity, attended, or not, with complete unconsciousness. These are quite analogous to the delirium succeeding the grand mal, but are more likely to become the subject of legal enquiry on account of the comparative absence of convulsion. (3). Attacks of clonic convulsions of the limbs, trunk, or face, without unconsciousness (Trousseau). (4). Attacks of motor paralysis, attended with pain and anæsthesia, without unconsciousness (Russell). (5). Attacks commencing with severe pain, and attended by some amount of paralysis (Russell). Epileptiform neuralgia, which Trousseau regarded as allied to epilepsy by its intractability and the suddenness and brevity of its paroxysms, might be regarded as another form of the malady affecting chiefly the sensory nerve-apparatus.

The treatment of epileptic hemiplegia will not be always the same. Many cases may call for very little. Many may require tonics or analeptics. I can quite believe that in some where the patient is plethoric, and determination of blood to the head (as I have seen) persists for many hours after the attack, a moderate cupping to the neck might be desirable, unless hot pediluvia and purgatives proved sufficient. Hyperæmia of a paralysed and unconscious brain, I should fear, might be a cause of serious mischief. Here, as ever, remember that each case must be treated according to its individual requirements.

Original Communications.

PURPURA.

By W. H. BROADBENT, M.D.,
SENIOR ASSISTANT-PHYSICIAN TO ST. MARY'S HOSPITAL.

(Read before the Harveian Society of London.)

THE object of this paper is not an exhaustive discussion of the diseased condition known as purpura, but simply to describe it as it has come under my observation, chiefly in the out-patient practice of St. Mary's Hospital, and to mention some of the considerations which have been suggested by the cases I have seen.

The name purpura is given to a state of system characterised by extravasations of blood in the tissues of the skin which give rise to brown or purple spots of various size. The spots are readily distinguished by the absence of elevation, and by the fact that they do not disappear on pressure, and are not rendered at all pale by it. In treating of purpura as a disease, I leave out of consideration, on the one hand, true scurvy, and on the other, those cases in which the purpuric extravasations are secondary to disorganisation of blood and tissues in the course of other diseases.

The pathological cause of the cutaneous extravasation is primarily some altered condition of the blood, this being shown by the fact that in the absence of special causes the manifestations are symmetrical. The precise nature of the alteration is not known, but it is not merely impoverishment, since this may be carried to an extreme degree, and may arise from the most varied circumstances without giving rise to purpura. But, secondary, to the change in the blood, there is also a change in the tissues, an undue lacerability of the capillaries, and it is this which permits of the extravasations, and not a disintegrated and dissolved state of the red-blood corpuscles. That a distinct and special deterioration of the structures is involved is shown by the fact that the seat of the extravasations is determined by mechanical conditions. The spots appear, for the most part, earliest, and are most abundant on the legs where the vascular pressure is greatest. This may be contrasted with the eruption of small-pox, or the petechiæ of typhus, which, being dependent solely on the blood-disease, are not influenced by hæmostatic pressure. Another evidence of the impaired tenacity of the capillaries is the production of large bruise-like marks by very slight injuries.

It is scarcely necessary to observe that purpura is not, in any sense, a skin disease. The extravasation may occur in the various mucous surfaces, when the name P. hæmorrhagica is given, or in the substance of organs.

The change in the blood and secondary alteration in the tissues, is not the same in all cases. We may refer, as an illustration, to scurvy, which, in virtue of the cutaneous extravasations and mucous hæmorrhages, is purpura, but in its known definite causation, and in the peculiarity of associated symptoms, is entirely distinct from the purpura of which I am speaking. In the same way, but in a minor degree, diversities in the apparent cause of the affection, in the mode of access, appearance, and progress of the eruption, and in the accompanying symptoms, indicate some difference, not in degree merely, but in kind, in the pathological condition.

The spots vary much in appearance in different cases, while they commonly adhere more or less closely to one type in the same case. In some they are circular, sharply defined, and, at first, of a deep blue or purple colour, and when they have this character, they are usually small. In others they never have so deepa tint, but are rather of a deep brown than purple colour, often larger in size, and less regular in form and outline, and they do not seem to involve so deeply the structures of the skin. In others, again, as in P. urticans, the patches are deeper in colour at the centre than near the periphery, gradually shading off into the surrounding skin, and frequently, even when first appearing, they have the dusky hue which marks a later stage of the more common variety of spots. Sometimes intermingled with the purpuric spots, there will be large vesicles full of bloody fluid, which break and leave dark coloured superficial ulcerations apt to bleed.

Sometimes a single—more or less copious—crop of the eruption appears at once, and dies away gradually without being succeeded by others ; or, as one crop is fading, or when it has disappeared, another will follow. In these cases, all the spots seen at any given time will be in the same stage. In other cases, there will be a succession of scattered spots, so that they present themselves in all stages. The duration of individual spots is not very different. The abnormal condition of the textures does prevent the blood from being absorbed, and as this process goes on, the patches undergo changes in colour, and at length disappear. The duration of the disease depends on the coming out or not of successive crops. A peculiar

method of eruption is that seen in P. urticans, as it is called. Red, congested, slightly elevated patches appear usually on the legs, or on the legs and forearms, resembling somewhat the wheals of urticaria, whence the name urticans, but as I have seen them more like the eruption of erythema nodosum. These swellings subside, leaving purpuric spots, which, however, as has been mentioned, are a little different in appearance from those usually seen, as they are also different in their mode of origin, being preceded by inflammation, and not being due simply to a rupture of capillaries.

These diversities in the character of the eruption, and in its mode of access, are commonly associated with different series of symptoms, but my observation has not been sufficiently extensive to warrant me in subdividing the disease, and classifying varieties in accordance with those differences.

One of the most interesting questions in connection with purpura is its causation. It would be instructive to institute a careful examination of all the classes of cases in which cutaneous and internal extravasations of blood of true purpuroid character occur — such as obstructive, heart-disease, in which, however, it is so exceptional that some other factor, in all probability, enters into the production—liver-disease, and especially acute atrophy of this organ ; phosphorus and arsenic poisoning in which notable tissue degenerations are found ; true scurvy, still very common in the merchant navy, and of which I have seen typical examples in London. This inquiry, however, does not come within the scope of the present paper, which deals only with that class in which the purpura is the prominent and primary feature of the diseased condition. The first question which suggests itself is as to food. It is very rarely, indeed, that the disease is traceable to the absence of any important article of diet. Sometimes, but not at all commonly, it seems to be in some measure due to general insufficiency of food. Habits of drinking have seemed to give rise to it occasionally, and I have met with it in persons under the influence of lead-poisoning. It is not uncommon to find it associated in women with catamenial irregularity ; and when a purpuric tendency exists, the manifestations usually take place at the menstrual period. Purpura has been observed to follow acute rheumatism in many instances, and is often associated with sub-acute and chronic rheumatism ; and I am inclined to consider purpura and rheumatism as closely allied conditions. Purpura is very commonly accompanied by pains which are rheumatoid in seat and character, and is frequently clearly traceable to the causes which ordinarily give rise to rheumatism, exposure to wet and cold.

The cases now to be given, will illustrate the various points advanced.

As has been said, something more than mere innutrition is implied by the presence of purpuric spots since this condition may be carried to an extreme degree, and may arise from the most diverse causes without bringing about the particular deterioration of the capillaries which permits of their ready rupture. But in out-patient hospital practice, cases are often met with in which general debilitating causes, insufficient food, over-suckling, &c., have been at work, and have evidently had a large share in the production of the disease. When this is the case, the spots come out, not in well-marked crops, but more or less freely on any exciting occasion occurring, such as a hard day's work, prolonged standing, the catamenial period.

Of this sort is the following :—

Ann W., æt. 40, wife of a stableman, and residing in Mews, had for some time been living poorly. She applied as out-patient at St. Mary's Hospital, on August 13th, 1866, complaining of weakness and pain in the head. On September 6th, the legs were swollen and painful, and presented numerous purpuric spots. This was her catamenial period. The swelling of the legs continued, and she had still much pain in them on the 13th, but the spots had faded. On the 20th, new spots had come out, but on the right leg only, where the veins were large. The treatment was iron and quinine, with dilute sulphuric acid, and a supply of good food from the St. Mary's kitchen. On the 27th, the eruption was no longer visible, and it did not return. Pain and swelling of the ankles continued for some time, but she was discharged on November 22nd better in all respects.

A similar case is that of

Margaret N., æt. 35, wife of a labourer living in Suffolk-place, an unhealthy court in Marylebone. She applied on Feb. 22, 1866, having just weaned of a child of fifteen months, and in addition to the usual consequences of over-suckling, weakness, pain in the loins and shoulders, and sense of sinking, &c., had, at every menstrual period, swelling of the legs, and an extensive purpuric eruption of the diffuse character. She improved rapidly under cod-liver oil and iron, and ceased to attend on April 24th.

Other similar cases might be given, but these constitute the least interesting class, and most commonly purpura is not associated with any such degree of general debility, and cannot be traced to the ordinary causes of this condition. It will come on suddenly when the patient is apparently in good health, and may be unattended with any marked degree of muscular weakness, in this contrasting with scurvy, which is gradual in access, and is always attended with muscular weakness and nervous depression.

Examples of this kind are the following:—

Robert B., æt. 5, the child of a police-constable, was brought to the hospital Feb. 19, 1866. He had been getting a little thin for a short time, but otherwise seemed to have nothing the matter with him, till the nates and lower extremities were suddenly covered with small dark purpuric spots. The eruption was accompanied by aching of the legs. Castor oil was given to relieve the bowels, as they were constipated, and six minims of muriated tincture of iron four times a day. No new crop came out. The spots first seen faded and disappeared, and the child was soon quite well.

Richard B., æt. 32, a mason, became an out-patient on March 18th, 1867. He had been a great drinker up to eighteen months before, but since then had been a teetotaller till shortly before the attack, when he had a month's bout of hard drinking. He was working up to the day on which he applied at the hospital. For a fortnight purpura had been gradually coming out on the legs and forearms. On the legs the patches were very large, and on his hands black bullæ appeared. The legs and hands were swollen, and his joints stiff. He continued to work at his employment while under treatment, and soon ceased to attend.

George B., æt. 39, a carpenter, applied as out-patient on May 30th, 1867. A distinct blue line existed on the margin of the gums, otherwise he seemed to be in good health. A copious purpuric eruption had appeared on the legs, attended with soreness in these limbs, especially the right. He also was quite equal to his work.

I have referred to the relation which seemed to me to exist between purpura and rheumatism. In the cases just given there was pain and swelling, chiefly in the affected parts, but very frequently the pain is not confined to the locality of the eruption, but is felt in other parts of the body, and especially in the joints. Sometimes the pains have a wandering character, will be felt chiefly in the back and limbs, and after lasting a week or ten days, will cease, leaving the patient weak and languid, and then the eruption will make its appearance, constituting thus a stage resembling the prodromatous stage of fever, or a severe form of the disturbance of the system, which sometimes precedes or accompanies the manifestations of syphilis. But the pain may be much more prolonged than this, and may in all respects so closely resemble sub-acute or chronic rheumatism, that the treatment for this affection is unhesitatingly adopted, unless the existence of the eruption is known.

Frances C., æt. 47, applied at St. Mary's Hospital, August 16, 1866. She had been in good health, had lived well, and resided in a healthy neighbourhood. Severe pain had come on in the joints, attacking successively the hands,

arms, knees, and feet. She was scarcely able to walk. The case had quite the aspect of sub-acute rheumatism, and iodide of potassium was given in doses of three grains.

On the 20th a purpuric rash had made its appearance on the leg; the pain still persisting. The iodide continued.

27th.—The pain no better; scarcely able to walk. The first spots had faded, but another crop had appeared. Iron and quinine now replaced the iodide. The patient soon ceased to attend; her prior condition at her last visit was not noted.

Jas. H., æt. 38, a carpenter, became an out-patient under me, July 30, 1866. He had lived well and had enjoyed good health. Ten years previously he had been in the habit of drinking to excess, but not within that time.

Seven weeks before, without any distinctly assignable cause, he had been taken with great pain in the ankles and knees, which lasted about a fortnight, and then small swelling began to appear on his legs and fore-arms towards evening, which were gone in the morning, leaving purpuric spots. He felt very weak. The muriated tincture of iron was prescribed, but during a short absence from town in the early part of August, iodide of potassium was substituted by my clinical assistant. On August 13, iron was again given in the form of sulphate with quinine, and dilute sulphuric acid.

August 16.—Spots continue to appear on the legs, thighs and fore-arms, and small, superficial, dark-coloured ulcers, left by bullæ which had burst, were also present.

23rd.—An opportunity afforded me of seeing the eruption in its early stage. On the legs, fore-arms, and wrists, were spots resembling perfectly those of erythema modosum; slightly elevated; firm to the touch, and of a deep-red colour. These bear the purpuric stains. He feels better, but cannot stand more than three hours' work, and at night he has a sensation as if the blood would burst out of his legs. Tinct. ferri. mur. ʒxv., and acid sulph. chl. ʒvi., in water, was now given.

From this time he improved rapidly, but on Sept. 10th, after great exertion, many spots came out on the legs, and the skin was tense and swollen. The eruption was visible when he came to the hospital on the 13th, and below the knees the entire skin had a greenish yellow tinge. He was, however, stronger.

Sept. 17.—Better and stronger; very few new spots; soles of feet swollen and painful in a morning, but better after walking.

He came to the hospital for the last time on Oct. 1st, having resumed full work. A few spots had appeared at first, not afterwards.

Jas. H., æt. 33, a sailor, became out-patient at St. Mary's Hospital, Feb. 25, 1867.

After rough weather in the Mediterranean two months before he was in the hospital at Gibraltar for five weeks, suffering from rheumatism. He had been well supplied with food, but had had to sleep in a wet berth. He left Gibraltar well, but on reaching England began to suffer from pains in the knees and ankles, which became swollen after walking. In other respects he seemed well. Iodide of potassium was prescribed in doses of six grains. The pain diminished, but on March 11th purpura appeared on the legs, coming on with small swellings like "nettle stings." It was difficult to determine whether this was not a case of scurvy. There seemed to be a slight fulness and firmness in the popliteal space, and the gums, though neither spongy nor bleeding, had a red line on the margin, and were of a deeper tint than usual. The general condition, however, was not that of scurvy, and, though a sailor, the patient had not been deprived of fresh vegetables. He was ordered fifteen minums of tinct. ferri mur. in infusion of quassia, and improved rapidly.

It remains to show that exposure to cold and wet, the common exciting cause of rheumatism, is capable of inducing purpura. This, if not admitted as evidence of relation between the two diseases, is important, as showing what a profound general alteration in the blood and tissues may be brought about in this way; how changes such as those present in acute rheumatism or purpura are produced by a prolonged chill of the surface of the body; whether the primary affection is an impression made on the nervous system, or some influence exerted on the organic operations is not easy to say.

In several of the cases related, exposure to wet and cold was the only assignable cause of the purpura, but the connexion was not sufficiently obvious to be of any great value as evidence. In the following example the causation seems clear and undoubted:—

Henry R., æt. 26, a porter, became an out-patient at St. Mary's Hospital, September 10, 1867. He was a married man, steady and sober in his habits, living well on varied diet, strong and muscular and in good health, till 14 days before he had got wet through. Since that time he had never felt well. First, all his limbs were stiff and painful, so that he could scarcely move them. In a few days the pain passed off, but he felt weak and ill. Then, on the day previous to his admission, his mouth began to bleed, and purpuric spots appeared on his arms and legs. It is worth while to note the exact time, about twelve days occupied in the production of this deterioration of the tissues. The spots were circular, well-defined, of the size of a split-pea, and deep purple in colour. There was also a very large bruise-like mark on the forearm. His gums were bleeding freely, and in the mucous membrane lining the cheeks, especially opposite the line of the teeth, were large purple patches of ecchymosis. The patient was pale and felt weak.

He was ordered T. ferri. mur. ʒxv., acid. sulph. dil. ʒviii., mist. quinæ ℥j. + , and was recommended also to take two lemons daily in the form of lemonade.

He gradually improved, and was soon able to return to work.

Thomas K., æt. 24, a bricklayer, applied at St. Mary's Hospital November 18, 1867. Three weeks previously, after being engaged in work which required him to kneel for a long time on cold damp stones, and in the course of which he felt the cold very much, he was suddenly seized with pain in the knees and ankles, which became swollen. The pain continued, and a few days before he came to the hospital purpuric discolourations appeared on the legs. When first seen the legs were thickly covered with large brown spots, in many places confluent. Less distinct spots were seen on the backs of the hands. He took iron, with acids, and rapidly improved.

Another case, one of the worst examples of purpuric hæmorrhagica I have known to recover, was traceable to cold and wet:—

The patient was a boy, aged about 14, who was under my care, at the Free Hospital. He had been in good health, and had lived well, till shortly before his admission he got wet through. He had pains in the limbs, and fell ill, then the entire body became covered with large purpuric spots, and he began to lose blood from the mouth. He was at once brought to the Hospital. Every part of his body and limbs presented large purple blotches, and, at many points, the cuticle was gone, and large superficial bleeding ulcerations existed. The mucous membrane of the mouth was everywhere black, swollen, and bleeding, and the fœtor from the blood decomposing under the influence of the fluids of the mouth was most offensive, resembling that of gangrene. The poor boy presented a pitiable spectacle. The sheets all stained by the hæmorrhage from his numerous wounds, and the pillow saturated by bloody fluid issuing from his mouth. It did not seem possible that he could survive, but, fortunately, he could swallow, and there was no loss of blood from the intestinal canal. I prescribed tinct. ferri mur. with dilute sulphuric acid and quinine every three hours; ordered him port wine, and as much lemonade as he would drink; beef-tea and milk as food. At my next visit he seemed weaker and more haggard, but the bleeding was not so great. After this there was no doubt as to the improvement, and eventually he recovered.

The treatment of purpura has been sufficiently indicated in the cases given, and though, in many instances, the disease tends to a speedy recovery, it has seemed to me that the iron and mineral acids have conduced, in no small degree, to this result.

REPORT ON OZONE.

By H. DAY, M.D.,

PHYSICIAN TO THE STAFFORD COUNTY INFIRMARY.

(Read at the General Session of the St. Andrews Medical Graduates' Association.)

SINCE the year 1840, when Schönbein commenced to place before the world his researches on "electrified air," "ozone," or, as it has since been called, allotropic oxygen, no smaller subject than this has occupied the attention of scientific men.

The subject has engaged the attention of three classes of observers—the physicists, the chemists, and the physicians. The physicists have been struck by the bearing of the question in relation to the general phenomena of the universe—by the changes, as it would seem, which mere matter may be made to undergo under the influence of force. For, and from this reason, too, their minds have been brought to the consideration of analogous phenomena, noticed in the transmutations of phosphorous under the influence of heat; and some kind of countenance has been given to what may be called the ancient-modern notion which the alchemists believed, and a Faraday did not disbelieve, that a day will come when elementary forms of matter will be reduced to a few simple types, if not to a single one.

To the chemists the subject has been of interest, in that they have found a new body to attract their attention—new compounds springing from it—new views respecting the molecular condition of elements—new speculation as to combinations, and the expression of combinations by symbols and equivalents.

To the physicians ozone has afforded a wider, I had almost said a wilder, field; they have believed they saw in it a cause of disease—a remedy for disease—a preventive of disease. It has been obtrusive—it has been perplexing—it has been a subject of vast erudition, and yet it is up to this day a subject of intense doubt. Whilst some hold it almost in wonder, others are heretic enough to dispute its existence altogether, the majority hesitating and asking for more light.

During the time I have been writing this paper all these phases have been presented to me, and it is a singular circumstance, but quite true, that two brothers, both physicians of eminence, one residing in this country, and the other at the Antipodes, and both connected by the common tie of our University, are as widely separated in opinion on the subject of ozone as they are in the geographical limits of the world.

How then shall I (who have no pretence to be a judge of matters of such profound importance) proceed to speak in this assembly. I know of but one course, that is, to proceed as I have learned, determined at the onset not to embarrass myself with any anxieties as to who is right and who is wrong.

HISTORY.

That we may be carried on smoothly from one point of our study to another, let me briefly relate the circumstances connected with what is considered to be the discovery of the nature of ozone.

The earlier electricians appear to have formed an idea that common air did not admit of electrization; for instance, Benjamin Franklin, whose researches in electricity are second to none, says, in a letter addressed to Peter Collison, F.R.S., of London, in 1749, "Air is an electric *per se*, and, when dry, will not conduct the electrical force; it will neither receive it nor give it to other bodies, otherwise, no body, surrounded by air, could be electrified positively and negatively; for," he argues, "should it be attempted positively, the air would immediately take away the surplus, or, negatively, the air would supply what was wanting."

In the main, there can be no doubt Franklin was correct. It is clear that air can never be so electrified as to become either a conductor of electric currents, or an intense conductor of electrical force; if it could, what Franklin said would be true, the air would be the prime conductor and the prime holder of all electrical force; it would neither insulate the wire of a telegraph nor permit the largest machine to charge the Leyden Jar. But the generalization of Franklin was rather too sweeping notwithstanding.

It will be remembered that he wrote the above before the time of Priestly, and that in speaking of air he included under that term what he believed to be an elementary body, and so far was he right, that even now, with our knowledge of the compound nature of air, and the capacity of one of its elements—oxygen—to be influenced by electricity, and with electrical apparatus of the most powerful kind at our command, we can only affect one part in twelve of that oxygen which forms only one-fifth of the atmospheric scene.

The discovery of oxygen by Priestly led, after a few years, to the revision of the Franklinian hypothesis, as to the absolute incapability of the air to be influenced by electricity.

In 1789 Van Marum, an electrician of Holland, practising on the "vital air" of Priestly, or, as it has since been named—oxygen—discovered that after electric sparks had been passed through this gas, a peculiar odour was developed, which he spoke of as an "electrical odour," and which represents what has subsequently been called, on the same nomenclature, but from a Greek derivation, "ozone."

Towards the beginning of the present century Cavallo seems to have made a further step, for he observed that a peculiar condition of air was produced when passing through it electric sparks, which condition he designated the "aura electrica." Cavallo further observed that this electrified air had a purifying effect on decomposing organic matter, and he therefore had it applied, as he thought with good effect, to fœtid ulcers of the human subject. One of the discoveries about this period having an indirect bearing on the subject before us, deserves mention, the more so, because it independently confirms some more recent observations made by two of the latest experimentalists. The discovery I refer to was made by Aldini, the nephew of Galvani, and Professor of Experimental Philosophy in the University of Bologna, and who became celebrated in this country by his remarkable experiments with galvanism on the bodies of executed criminals. Aldini observed that when by means of a metallic point he electrified the interior of a glass jar which he inverted and placed over a plate of metal, so as to form what he called an "*insulated plenum*," the water in the glass rose, in a little time, several lines: afterwards he repeated the experiment, using mercury instead of water, when he observed the same occurrence, but in a less marked degree. In these experiments, evidently without knowing the meaning of the facts he had observed, Aldini saw the condensation of oxygen under the influence of electricity.

Nearly forty years now elapsed before any further notable advance was made, then Schönbein, the late well-known physical philosopher, commenced his famous researches; and taking the view that the electrical modifications of air rested solely on modifications of the oxygen, proceeded at last to theorise that oxygen itself presents three distinct conditions. The first, a negative polar condition, which he termed ozone; secondly, an opposite condition, which he termed antozone; and, thirdly, a neutral state, resulting from the union of the two.

It was fortunate for Schönbein that his researches very early obtained the attention of Professor Michael Faraday, who, although he attempted but little in original research in this one direction, made the scientific public, by his brilliant lectures, most familiar with what had been done, and excited many observers to prolonged and careful study.

The presence of a peculiar body, possessing special properties, once established by Schönbein, its nature became actively canvassed, and our countryman, Williamson, started the theory that ozone was a ter-oxide of hydrogen. This theory, based on the supposition that water was always produced when ozone was removed, assumed the absolute necessity for the presence of hydrogen for the production of ozone. It remained for Andrews and Tait to dispose of this view by proving that when hydrogen was entirely removed and absolute oxygen made to receive the electric spark, the change of oxygen into ozone, to the extreme extent of one part in twelve could be demonstratively established. The same observers further proved by after experiment, that in this process of change there is condensation of the oxygen and reduction of volume. Finally, they proved that when mercury was exposed to ozonized oxygen, the ozone disappeared, the volume of oxygen gas remaining precisely the same.

The last theory as to the nature of ozone, and which brings us up to our present knowledge of this curious gas, has been advanced by Dr. Odling, and confirmed experimentally by M. Soret.

The facts bearing on this point have been most ably epitomized in a leading article in the *Medical Times and Gazette* of October the 5th, in the present year, in the following words :—" It is now conceded by nearly all chemists that each molecule of oxygen in the free state consists of two atoms—that, in fact, the true formula for free oxygen is O_2. Odling suggested that the formation of ozone might really be the condensation of another atom of oxygen into each molecule, and that the formula for ozone might therefore be O_3, and its density one-half greater than oxygen. When 100 volumes of oxygen were reduced by ozonization to 92, it might be supposed that 8 volumes of oxygen, combined with 16 volumes and produced 16 volumes of ozone. The change might be represented in this way :—

$$40_2 + 80_2 = 80_3,$$

" A molecule of ozone O_3 occupying the same volume, as a molecule of oxygen O_2. The absorption of the ozone by mercury, iodine, &c., might really be only the removal of the third atom of oxygen, which would of course leave the volume unaltered.

16 Volumes. 16 Volumes.

$$80_3 + 8Hg = 80_2 + HgO.$$

" The same view would account for the mutual reduction which ozone and peroxide of hydrogen exercise upon one another, and, in fact for all known reactions of ozone.

Ozone. Peroxide Hydrogen. Oxygen. Water.

$$O_3 + H_2O_2 = 2O_2 + H_2O$$"

This beautiful hypothesis, however, must have remained a mere hypothesis, but for the remarkable experimental verification which it has received from the hands of M. Soret. We have seen that all ordinary substances are only capable of removing one atom of oxygen from each molecule of ozone; but Soret has at length found a body, oil of turpentine, which absorbs the whole molecule, the whole three atoms of oxygen. To take our previous illustration, if the 92 volumes of ozonised oxygen were treated with oil of turpentine, a dense white cloud would appear, the ozone would disappear, but instead of the volume remaining the same it would contract to 76 volumes, the $16O_3$ having been removed bodily, instead of being merely reduced to $16O_2$.

" This experiment (the writer says) seems to place the matter beyond a doubt, and instead of the mass of hypotheses which so lately reigned, we have now a simple, beautiful, and coherent theory which affords an intelligible explanation of known facts. It is the more to be rejoiced at, since the importance of ozone in art, as well as nature, seems to be rapidly developing, and it is impossible to say how high that importance may rise."

One or two more points, and my narrative respecting the nature of ozone must be concluded.

In the first place I would remark that the hypothesis of Schönbein respecting the three distinct states of oxygen has fallen into disfavour. Secondly that the manifestation of ozone as a distinct body can only be demonstrated within certain limited degrees of temperature. At what reduced degrees of temperature ozone may become manifested is a question as yet unsolved, but, that it disappears at an elevated temperature admits of direct proof.

In common language, then, ozone is destroyed by heat, but, it is possibly more correct to say, that it loses its character, or certain of its special characters. Why this should be so is altogether unexplained, except on the supposition of a transmutation of force.

MODE OF PRODUCTION.

Several means exist for the production of ozone besides those natural means, whatever they may be, which bring it into the air without our calling for it.

Amongst the several artificial modes, the first to be mentioned should be the original one of passing the sparks of an ordinary frictional electric machine through the air, or, through oxygen : an improvement on this method has been introduced by the use of Ruhmkorff's induction coil, which we have here before us. When sparks are passed between the electrodes of this machine the air is ozonised, but in order to collect the air thus ozonised it is necessary to add to the machine what is called an " ozone generator." Siemen was the first to use the " generator," his instrument consists of two cylinders of glass, covered, or rather partially covered, with tin foil, one cylinder being enclosed within the other, there being a space of about half an inch between them. A wire from one of the electrodes of the coil passes to the tin foil of the inner cylinder, and the wire from the other electrode passes to the foil of the outer cylinder. When the coil is in action electric sparks are freely discharged between the two cylinders, and when a current of air is driven, by a pair of bellows, through the space in which the discharge takes place, the air is freely ozonised. An improvement on Siemen's apparatus has been constructed by Mr. Apps, the Philosophical Instrument-maker in the Strand. A sectional drawing of it is here, and the instrument itself upon the table. If, now, we set the coil in action, drive air, with the bellows, through the ozone generator, collecting the ozonised air in bottles placed in the pneumatic trough, we can rapidly fill several bottles with air saturated with ozone.

The odour of ozone may very readily be detected for sometime in these bottles. Workers in ozone will forgive me for this simple experimental illustration, but, as this is the easiest way for producing ozone, and it is my wish to familiarize every one with the process, it could not very well be left out. For all experimental researches this is by far the best and readiest mode of production.

Another method of production consists in passing air over phosphorous partly immersed in water. A simple ozone maker of this kind was invented by the late Dr. Barker, of Bedford, and another, I believe, by our colleague, Dr. Moffat, of Hawarden, whose researches on the relations of ozone to disease are so widely known.

Another mode of production, not very applicable, but forming a pretty experiment, consists in diffusing the vapour of ether through a bell-shaped jar, and then inserting in the vapour a heated glass rod.

The last suggested method is one by M. Morin. It consists in dispersing a current of water in the pulverized form, in other words, in the form of spray.

These are some of the principal artificial means of obtaining ozone ; of the manner in which it is produced in nature, various theories have been suggested. Dovè, so well-known for his theories on the laws of storms, thinks that ozone is generated in the higher currents in the atmosphere ; in fact, during the condensation in their polar course of the heated equatorial currents. Moffat believes he has traced the ozonic atmospheric periods to particular winds, and also to certain phosphorescent states. Lowe holds that the apparent varying intensity of ozone may possibly be attributed to circumstances operating for

or against its detection ; thus, an increase of temperature, from increased chemical action, would show an increase, a greater velocity of air, an increase, of moisture up to saturation, after which a minimum will result. At his (*i.e.*, Lowe's) observatory at High-field House, near Nottingham, most ozone occurs during the prevalence of a south wind, and least with a north-east wind, the maximum being attained when the barometer is at its lowest readings, and the minimum when at its highest; this, he thinks, may be simply owing to the increased velocity of a south wind over a north-east wind, its increased temperature and its moisture. Others have argued that ozone is the result of electrical discharges in the air, and several have assigned to vegetation the generation of this gas, amongst these last, I may name Dr. Daubeney, of Oxford. Dr. Daubeney, judging from the depth of colouration produced upon Schönbein's papers, by exposure to the open air, as observed during eight months, inferred that the quantity of ozone at Torquay was much greater, on the average, during the prevalence of winds from the sea. He also endeavoured to ascertain whether this ozone was generated by vegetation, and, although he found that light alone coloured the paper, he was led to infer that, after deducting this, a certain residual effect was due to the green parts of plants in generating ozone during the day.

Presuming that the opinion of M. Morin is correct, and that ozone can be produced by the spray of water, the prevalence of ozone during sea-breezes might possibly be traced to the action of sea-spray.

In order to ascertain whether there was any plausibility in this last named theory, I tested the influence of spray with fresh and sea-water, using Richardson's spray-tube for the purpose of diffusion, and directing the spray on plates of ozone test-paper. I first used *distilled water*, and kept up, vigorously, a continued spray upon the paper for five minutes, but without producing any change of colour that indicated the presence of ozone. I next used *rain water*, the specific gravity of which did not appear to differ materially from that of distilled water. The spray was continued for the same length of time as in the former experiment, and with a similar result. I now used *river-water*, obtained from the river Penk. The specific gravity of this was 1·006. The effect on the paper corresponded with that produced in the two former instances. I then tried *sea-water*, having a specific gravity of 1·268. The spray was in this, as in each instance, continual for five minutes, and at the expiration of that time, I fancied there was an appreciable difference in the colour of the paper, but the alteration,—if alteration it might be called—was so faint, that I thought it desirable to repeat the experiment, and upon doing so, only obtained the same effect as that displayed with the three previous waters. I next dissolved sufficient Tidman's sea-salt in ordinary pump-water until it attained the same specific gravity as the sea-water. It was used in precisely the same manner as the other waters, and with no other effect than they produced. I, of course, used fresh test paper for each experiment. As far as these experiments go, and taking them for just so much as they are worth, the result given was altogether a negative one ; it must, however, be borne in mind that experiments of a somewhat similar kind, on a larger scale and better devised, might possibly afford evidence confirmatory of M. Morin's views.

As regards the general question of the natural production of ozone many difficulties stand in the way of its solution : so many bodies present in the air, produce such similar effects ; light, as Dr. Daubeney observed, is a source of interference, and the circumstance under which the ozone seems to appear are so disconnected and variable, that I regret to be unable to report any solid progress in this direction. When we are dealing with artificially produced ozone, we are treating a tangible body, and we can remove nearly all obstacles to investigation ; but in dealing with air, the position is entirely different, and uncertainty, instead of certainty, meets us in every foot of our research.

(To be continued.)

TREATMENT OF BURNS.

By HENRY MAC CORMAC, M.D., L.R.C.S.Edin.

When the cutis is laid bare in consequence of wounds, abrasions, blisters, burns, or scalds, one of the elements of the accruing pain arises from the caustic action, if we may term it so, of the atmospheric oxygen. Hence, a pressing indication, in respect of treatment, is to exclude the air. The greater or less vogue of certain popular remedies, as carron oil, flour, raw cotton, and others, is to be ascribed to the exclusion of the outer atmosphere. Freshly rendered lard is deserving of a prominent place in this list. I found this substance, to wit—recent hogslard rendered without salt, very useful sometime since in the case of a poor child of seven years of age, in a miserable state, owing to a compound burn and scald.

Dr. Purefoy has, recently, in the columns of the Medical Press and Circular, advocated the employment of the bath, in the treatment of extensive burns. When we reflect how useful the prolonged employment of the bath has proved in various cutaneous affections, the inference that it would prove useful in burns, seems well borne out. Dr. Purefoy speaks of the relief which *cold* water affords, when a burnt surface is immersed in it. Here, the lowering of the temperature and the shielding of the part from the atmospheric oxygen, prove severally useful. It would not do, however, to immerse the whole body, at least for any considerable period, in cold water. The temperature of a bath which was to be kept up for whole days, or perhaps weeks, should not be less than 100° Fah., or the natural temperature of the living human frame. And the water, further, would need continual renewal day and night. The water would prove the very softest cushion and dressing imaginable, and, as it would lose by weight as much as the weight of the water which it displaced, the body immersed could be readily moved without the torture which burnt persons now experience when displaced for any purpose.

OBSERVATIONS ON BRADEIKINESIS, OR RETARDED POWER OF MOTION AND THE USE OF THE ESTHOCLINE.

By EVORY KENNEDY, M.D.

The surgeon occasionally has presented to him a case of curvature of the spine, confirmed and incurable, which depends upon causes quite within the range of our art to remedy, if the pathology of the disease be understood, and the proper treatment adopted at a sufficiently early period. We may, in the first instance, trace most of the cases of spinal curvature to disease of the bony structure or want of due balance in the action or power of the muscles which retain the column in the perpendicular posture. With both of these causes we are all but too familiar.

There is, however, another cause, that to which I now presume to draw your attention, and, as the spinal curvature is only one of the results of the diseased state, and generally only observed when the case is advanced, it will be necessary for practical purposes to deal with it as *sui generis*, to investigate the pathognomic characters of the original diseased state, and, when satisfied of its individuality by a just recognition of its special symptoms, to attach to it a name by which it may in future be characterised, and describe a treatment applicable to it.

Most practitioners have been consulted by parents whose children arrive at the usual period for moving about, without being able to do so. When a child don't, as it is naively termed, "put his feet under him," about the 12th or 15th month, the mother gets uneasy, and the doctor is consulted. His answer is a simple, and, in general, a wise one—"Patience." The child may be intelligent, well-formed, able to crawl about freely on the floor, but don't proceed beyond this stage.

When he is placed on his feet he totters, and his attempts at progression are futile, his limbs move under him only by a great effort, and yield to his weight as if made of jelly, and, with every inclination to change his position, after a few attempts, he gives it up in despair, and is fain to measure his length on the floor again, where alone he is in his element. This is the most ordinary form. But we have it in both a lesser and greater degree. As the best means of becoming familiar with the disease, better relate a case of the latter or aggravated form.

A peculiarly intelligent and precocious child, of about two years and nine months old, was brought to me some time since, carried in its nurse's arms. Its head bent forward, its shoulders and upper part of the trunk yielding in the same direction, converting the spine into an arch, with the keystone about the 4th dorsal vertebræ. It could not retain the perpendicular when replaced. It possessed the power of moving the arms, but languidly, and could crawl on the floor by drawing forward the trunk with the arms, and a curious lateral crab-like effort of the muscles of the trunk; but the power of the muscles in the lower limbs was so slight that it might be almost pronounced paralysed. Yet, the limbs were well rounded, the temperature natural, and the colour not bad—rather bloodless, but all the tissues of the limbs and body were soft, pliable, and flaccid. Its nutrition was not absolutely bad. Its power of speech was the most pronounced muscular power it possessed, and its intellect, as already mentioned, was precocious. The child, placed on the stomach, regained in a great measure a straight position, except at the 3rd and 4th dorsal vertebræ, where there was a fixed projection, the bodies of the vertebræ having been absorbed from the incessant habit of sitting erect in the nurse's arms, and on the bed, the only attitude it could be induced to retain, and which it perversely insisted upon despite every effort made to the contrary. On inquiry, I satisfied myself that this child had never had a fit; had continued from its birth to enjoy reasonably good health, except slight irritation from teething, from which it was suffering when brought to me, and that its power of motion had never been *greater*, but on the contrary there had been a very slight but perceptible *increase* of power with its increasing age. The parents attached evidently little importance to the spinal curvature. In fact it had not attracted their notice until I drew their attention to it, so gradual had been its progress, the result of the attitude so constantly maintained.

In order to arrive at a conclusion as to *what this case was*, the simpler plan will be to satisfy ourselves *what it was not*. It was not infant paralysis, because it did not display the history nor exhibit the symptoms of this disease. The want of power existed from the birth, and although so general, was more marked in the lower limbs, but it was not complete, as even these could be moved slightly under volition. There was no wasting of the limbs affected, as we so invariably see to be the case in those mysterious forms of what we may term the partial paralysis of children, which leads to so many cases of deformities in the limbs and spine in adult life—the temperature of the affected limbs.

The want of power had not been preceded, as had occurred in most of the cases that I formerly described, of paralysis produced by pressure or other circumstances connected with their birth, nor had apoplectic or cataleptic symptoms preceded it.

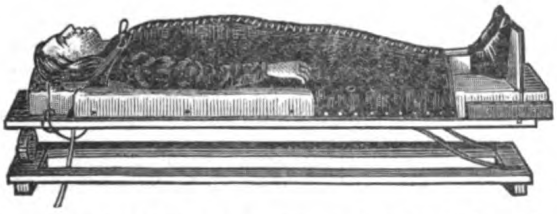
It had not followed, as we see in the paralysis of childhood, fever, gastric irritation, teething, or cerebro-spinal disease, or sympathies. In fact it was due to none of those causes to which paralysis is ascribable, and did not exhibit *its* history or symptoms; leaving us no alternative but that of pronouncing it a disease, *sui generis*, the essential or pathognomic characteristic of which is not loss of power in the voluntary muscles, but an original imperfection in that power, depending upon tardy or delayed development. We shall therefore denominate the disease *bradeikinesis*, or delayed power of motion, as best conveying in one word the idea necessary to its diagnosis, prognosis, and treatment.

Its pathology, I am happy to state, I have had no power of elucidating by dissection, as I have never seen a fatal case of it, nor, indeed, should I expect any structural alteration or lesion that would throw light upon it. Cerebration in the case above recorded was perfect, and no evidence of spinal lesion presented itself, although, from the defective power being more generally found in the limbs, we would naturally anticipate that should future investigation detect any lesion or structural alteration in this disease, it would show itself in the medulla oblongata. Although the cerebral development and mental powers were so perfect in the above case, it is not always so, as I have met some cases of bradeikinesis in which the brain was so small as to give the idea of idiotcy, and in which cerebration was most imperfect. In these cases it is fair to infer that whatever perceptible or imperceptible variation from ordinary structure or function exists in the medulla, the same variation must exist also in the brain, and what is confirmatory of this view is, that in these cases even of very small brains, the cerebration, like the motive power, is not absent or irrevocable, but merely retarded or slowly developed, and, did we want to distinguish that in which imperfect cerebration is the prominent characteristic, we might designate it in contradistinction, as "bradeinosis," or tardy mental development. The articulation is, in these latter cases, as we might expect, more frequently engaged, and for years they are scarcely intelligible, but gradually both cerebration and articulation develop, and I could, at this moment, point out more than one case of an able-bodied, reasonably educated gentleman, in the full possession of his faculties, heir to an estate, exercising all his duties, and talking, walking, and thinking as accurately as needs be, whom I have treated in his infancy and childhood, and who, at five years of age and later, either appeared almost an idiot, or staggered about or crawled with difficulty, or who could not give utterance to an intelligible sentence.

The treatment of these cases which (I should have mentioned earlier) are not unfrequently the product of intermarriages between cousins, is that usually applicable in cases of original constitutional delicacy, and may be best described as *tonic*. Nutritive food, animal broths, cream, farina; healthy, elevated, and dry residence; frequent changes of air, much better than a fixed locality, even though this be at the sea-side; carriage exercise and constant change of bed-room, with change of position of the bed with reference to the light, and objects that attract attention. The medical treatment—attention to the functions of digestion by regulating the food, so as to avoid repeated aperients. The administration of the most suitable tonics, either steel, bark, the bromides, cod-liver oil, &c., alternating them according to circumstances, and not continuing one too long. That which I have found most useful and capable of being longest persisted in, and returned to as an habitual medicine, is the phosphate of iron. The regular use of the bath, sea-water, if possible, and a permanent, never-ceasing habit of making the child exercise all the limbs, but particularly those most engaged. This is a matter of much importance, and can never be too much insisted upon. The simplest and most agreeable way of doing this, as far as the child is concerned, is to place it on a blanket on the floor, and encourage, by all manner of decoys, to crawl about on all-fours. The last and most important point in the treatment, however, is to prevent distortions of the body and limbs, occurring from mismanagement in the child's habitual posture. It will have been gleaned from what has preceded, that the curvature of the spine occurring in these cases is the effect—not the cause—of the disease. Every child at all able to accomplish taking the erect or sitting posture, does so when not asleep, and even children unable to assume it themselves, evince, at a very early age, the determination to be placed in that

position. This they do in a very simple and intelligible manner, by bellowing until their nurses place them erect. When the child is placed erect, the weight of the trunk and head being too great for the feebly acting muscles of the spine brings the spine into a curve. This posture is sustained either by the nurse carrying it about in arms, or leaving it propped up on the floor, generally whilst the child is awake—eventually the bodies of the vertebræ absorb to accommodate themselves to this posture, and an antero-posterior curvature is permanently established. The child, from habit, hastening the absorption by continuing to assume the curved posture even in the recumbent position when asleep, as well in erect posture when awake. All our rhetoric is thrown away upon the nurse in insisting upon the recumbent posture. She has every wish to carry out our directions. She places it in this posture as we direct, the child cries and struggles, she tries to soothe it, it cries more—she threatens, it cries more, and at length she yields, and either places the child erect, or allows it to assume the vicious posture. The child ultimately baffles nurse and surgeon, and succeeds in confirming a spinal curvature.

Repeated vexations, and most unsatisfactory cases of this kind, brought my attention to the devising some method of accomplishing the great desideratum of retaining the child in a proper attitude, independent of the nurse's solicitude, and its own volition ; and having succeeded in accomplishing this in a very simple and effectual manner, I should fail in my duty to humanity did I not place it at the disposal of the profession, for the treatment not only of the class of cases I have described, but of the many others in surgical practice to which it may be applicable. I here exhibit the apparatus, which you will per-



ceive consists of a lightly constructed and upholstered recline, with a hole cut for the head to fit into, and a footboard with a moveable rack to adapt to the heels. The essential part of the apparatus for our purpose, however, is the garment or cloth covering nailed at each side along the incline, with free sides perforated, and carrying eyelets, or with hooks like those used for rapidly lacing boots. These garments have arm-holes, through which the arms pass, so as to allow them free motion. The loose edges of the garments are, you will perceive, cut to take the shape of the human figure, and when placed in the incline, and these cloths laced together, the occupant is not merely thoroughly restrained in all his movements, save those of his arms, but he is sustained by an equable pressure at all points—that a stretch of our imagination might liken to atmospheric, but that it may suffice us to compare with the experimental frog imbedded in plaister.

Having quite satisfied myself that mechanically this was exactly what I required, I confess I looked forward with no trifling anxiety to the reception it would meet with from the first young prisoner with whom I tried it, a self-willed boy, of three years of age, that no persuasion, threats, or promises, could induce to remain for one moment in the recumbent posture. His muscular power was markedly improving under treatment, but the bodies of the vertebra were steadily absorbing, and curvature was established to a considerable extent. My satisfaction is not to be expressed when I found he not only submitted to be incarcerated, but absolutely enjoyed it.

In fact, a new life opened upon him, for his posture could now be changed in a variety of ways; he could be placed for a short time erect, for a longer time demi-erect, at any degree of inclination, and it was no trifling gratification to find this charming boy propped up and looking about him, apparently standing on a level with his little companions, and taking quite a position in his social circle.

Lest some of my hearers should imagine that the placing of children for any length of time in the apparatus described, would prove unsupportable, or even very irksome, I may bring to their recollection the adaptation of identically the same principle, and very nearly the same apparatus on a large scale in the nursing of infants in different nations of Europe, particularly in Switzerland and Italy, as well as amongst the North American savages, as so graphically described by Lord Milton and Dr. Chudle.

I shall not delay now to point out the many surgical cases to which this, or modifications of this, very simple apparatus may be applicable. Springs placed, as you perceive here, on a separate stand or frame, or it might be placed on a carriage, so that a child or adult with spinal or joint disease might take exercise in it. Handles attached make it a valuable and simple ambulance for the battle field, without the risk of displacement, as well as in diseases of the knee, hip, or other joints, or in cases of fracture, where change of air or change of posture is desired. It not merely prevents motion in the diseased part, but by the general support and pressure given over the whole body, it prevents those convulsive and involuntary actions of the sympathizing muscles, like bandaging in cramps, and retains the body and limbs at rest when the patient is carried about. If the back were solid, crutches and restraining springs could easily be adapted where a firm support was required to keep any particular part of a limb fixed. But these applications of it are so obvious, that glancing at them is sufficient; I shall, therefore, conclude this paper by giving this simple apparatus a name, the *esthocline* or garment-bed.

Hospital Reports.

ST. THOMAS'S HOSPITAL.

KNEE ANKYLOSED AND DEFORMED : CURE BY GRADUAL PRESSURE.

Under the care of Mr. SIMON.

MARY J., æt. 13, a healthy-looking girl, was admitted May 23rd, 1866, into Queen's ward, with the following history:—Three years ago, she was laid up with "scarlatina," which was followed by "abscess" in the knee. The latter kept her confined to her bed for a long time, and resulted in a stiff joint with considerable deformity. No sinuses formed at any time, and she did not suffer any actual pain in the knee, but it was always a source of annoyance and discomfort, and she was constantly falling down and knocking it.

On admission, the knee was quite firmly ankylosed by bony union, and the leg bent forward on the thigh at an angle of rather more than 20° from a straight line, so that the heel rested on the ground, and the toes were thrown up. It was also bent outwards about the same angle, and the tibia was thrown rather behind the femur. The patella however was not fixed. She came into hospital with the intention of having the leg amputated on account of its inconvenience, but Mr. Simon determined to try first the effect of gradual pressure by means of splints. The ordinary "long outside" was adapted, and in course of time, a Macintyré used with it, and then a special apparatus was obtained. These, however, did not seem to answer the purpose quite to Mr. Simon's satisfaction, and he ultimately made use of a child's long outside behind the limb and a jointed iron long outside on the outer side. This latter worked at the joint by means of an archimedean screw, and counteracted the lateral deviation of the leg. The former gradually rectified the flexion forward. Pads were placed behind the knee, and a bandage applied firmly over the whole.

The progress was extremely slow at first, but after the end of six or eight months, a slight improvement was visible. Three months after this, the deformity was manifestly reduced, and on April 18th, both lateral and antero-posterior deformities were very markedly improved, the latter particularly. When she was discharged from the hospital, June 14, 1867, thirteen months after admission, the limb was really straighter than the opposite one, which was always somewhat knock-kneed.

Remarks.—This case shows, in the first place, the result of negligence and inattention during convalescence from an acute disease of the knee-joint. It would appear that after the scarlatina three years previously, some acute form of disease attacked the knee-joint, and resulted in firm long ankylosis. This disease had evidently been synovial in its origin, and had not involved the bones in caries or in necrosis. But union had been allowed to take place in an unfortunate position of the limb, either from the friends' or the doctor's oversight, and the result was, that the leg was almost useless, and a source of great annoyance.

As regards the treatment, it is seen, that by very simple means, tried fairly, and with patience, a deformity of two or three years' standing, and apparently irremediable, was eventually cured. The means adopted were such as are available by any practitioner.

Another point of interest, is the manner in which improvement rapidly took place when once it commenced. As is seen, very little progress was visible for the first six months or more ; but during the last three months of her stay in hospital, the improvement was very rapid. An impetus being once given, progress was without difficulty increased, in accordance with laws essentially mechanical.

The age of the girl was in her favour, although this is a point of probably less importance than the age of the ankylosis, *i.e.*, the length of time which has ensued since the commencement of bony union.

The fact of the patella not being fixed, is evidence that the whole of the joint had not participated in the disease, but there appeared very little doubt, on examination, at the time of admission, that perfect bony ankylosis had taken place between the opposed surfaces of tibia and femur.

ST. GEORGE'S HOSPITAL.

CASES OF PYÆMIA ADMITTED IN 1866.

1. Joseph M., a fireman, æt. 28, admitted under the care of Mr. Henry Lee, on the 10th January. His thumb and two first fingers had been crushed by an engine-wheel, which rendered primary amputation necessary. On the 25th the first rigor appeared, and was followed by profuse sweating and dyspnœa. Though stimulants were given, the patient died two days afterwards. No post-mortem allowed.

2. Thomas J., 9 years of age, was received on the 15th January, with a lacerated wound of the leg and an injury to the knee. He was attended by Mr. Tatum. Phagedæna attacked the wound on the 16th day. When this ceased he was in a very low state. Opium, ammonia, bark, and brandy were severally administered. The first rigor showed itself on the 7th March, followed by exhaustion, and the patient rapidly sank. *Post-mortem.*—The knee-joint was laid open, when the cartilages were found ulcerated, and the femoral vein plugged. Secondary deposits also were found in both lungs.

3. Henry W., conductor, æt. 32, admitted January 25th, and placed under the care of Mr. Pollock, with stricture and retention of urine. On 3rd February a friction sound was heard on the left side of the chest. Next day the first rigor appeared, followed by profuse sweating and cough. Pil. col. c. opio, effervescing saline, and stimulants were given, but death occurred on the 10th. The post-mortem showed pus around the urethra and neck of the bladder, and secondary deposits in the lungs and kidneys.

4. George O., 51 years of age, came into the hospital on the 12th February, under charge of Mr. Tatum, with gangrene of a finger after injury. Amputation was performed, and in twelve days afterwards the first rigor came on, followed by profuse sweating. Bark, brandy, and ammonia were administered, but the patient died on the 4th March. No post-mortem.

5. Sarah H., æt. 57, married. When admitted on the 14th February she had abscess of the elbow-joint of five months' standing. Mr. Holmes took charge of the case. She had the first rigor on the 24th March, followed by profuse sweating. The skin became jaundiced, and diarrhœa supervened. Brandy, ammonia, and opium were administered, but death took place on the 30th. The post-mortem showed the bones of the elbow-joint carious, and a secondary abscess in the left lung.

6. Susan D., married, 48 years of age, was admitted under the care of Mr. Pollock, February 21st, with ruptured perinæum, causing prolapsus. The plastic operation was performed. On the 27th the first rigor came on, followed by sweating and prostration. Opium, brandy, ammonia, and effervescing salines were administered, but she died, notwithstanding, on the 3rd March. *Post-mortem.*—The lungs, liver, and spleen contained secondary deposits.

7. William F., æt. 28, had fallen from a scaffold, and was brought to the hospital, March 13th, with depressed fracture of the skull, without symptoms. He was placed under the care of Mr. Tatum. The first rigor came on the 4th of April, followed by profuse sweating. Stimulants were administered. He died, however, six days afterwards. On post-mortem examination, the inner table of the skull was found to be uninjured. There was pus in diplöe, and between the bone and dura mater. No other parts were examined.

8. Henry B., a carman, aged 40, was admitted June 5th, and placed in charge of Mr. Holmes. He had suffered amputation of the leg three years previously for a primary injury. On the 24th he had the first rigor, followed by sweating and secondary hæmorrhage. The rigors recurred, and he had epistaxis. Stimulants were administered, but he died on the 30th. There was no post-mortem.

9. William W., æt. 18, a bricklayer, was admitted on the 9th of June, under care of Mr. Holmes. A gun had exploded while he was drawing it through a hedge, and left a large lacerated wound of the thigh. He lay till the 26th, when the first rigor came on, followed by sweats, convulsions, and delirium. Brandy, wine, chlorate of potash, and bark were administered, but he sank and died on the second day after the first rigor.

10. William F., shoemaker, æt. 42, came into the hospital on the 16th of June. He had cut his finger with a knife, and thecal abscesses had supervened. He was placed under the care of Mr. Pollock. During the treatment, stimulants, bark, and ammonia were given. The first rigor ensued July 1, which was followed by profuse sweating, repeated shiverings, and jaundiced conjunctivæ with purulent expectoration. He died on the 10th of July. No post-mortem.

11. Mary L., æt. 30, married. Admitted on the 31st of Oct., and transferred to Mr. Pollock's care, Nov. 14. She has had eight children. Her last confinement was 22nd of June, and was followed by rigors and abscesses. Rigors occurred also six weeks before her admission. When transferred she had bed sores, and a purulent discharge from vagina, with abscess in the thigh. The abscess was opened, and brandy and beef-tea prescribed, but she died on the 20th of Dec. No post-mortem.

12. Uria C., 57 years of age, was admitted Sept. 7, and taken in charge by Mr. Pollock. His hand had been crushed three days previously by the pole of an omnibus. An abscess followed. On the 11th of Sept. he complained of pain in the ankles, and the left shoulder, where there was a swelling. The abscess was opened, and a puncture made in the shoulder. Brandy and ammonia were prescribed, but he died on the 14th. By a post-mortem, it was found that the lower part of the right lung was rotten

and congested, and the spleen pulpy. The left shoulder and knee-joints contained pus.

13. Eliza A. C. She was admitted under the care of Mr. Henry Lee, Sept. 12. She was a married woman, 53 years of age, with an abscess of the knee-joint of uncertain date. Amputation of the thigh was performed Oct. 11. On the 12th the first rigor came on followed by profuse sweating, and repeated shivering fits. Egg and brandy, wine, bark, were prescribed. She died twelve days after the operation. A post-mortem examination was made. There were secondary deposits in the left lung and right pleura. The stump was sloughing. There was a clot in the femoral artery almost destroyed by suppuration ; also osteo-myelitis of the femur. The inferior vena cava contained a broken-down blood clot.

14. Charles A., a surveyor, æt. 37, came into the house September 14th, and was transferred to the care of Mr. Henry Lee next day. He had an abscess of the elbow-joint of long standing. Oct. 3rd, the first rigor appeared, followed by sweating and exhaustion. Brandy and bark were given. He died Oct. 4th. Post-mortem showed both lungs congested posteriorly ; spots of intense congestion in the liver; abscesses in the kidneys; an immense abscess in the right thigh, with clots in the femoral and illiac veins.

15. William B., æt. 38, a fitter, received under the care of Mr. Pollock Oct. 8th, with a compound fracture of the leg. Secondary hæmorrhage occurred. Amputation of the leg was performed. The first rigor appeared Nov. 1st, followed by profuse sweating and vomiting. Maximum temperature 103·2; respiration per minute 28; pulse 136. Brandy, ammonia, and quinine were given. The patient died Nov. 18th. *Post-mortem.*—The stump was sloughing. There was pus in the femoral and profunda veins. The tongue was swollen, and œdematous on the left side, and there was an abscess in the left lung.

16. James D., a navvy, æt. 17, was admitted Oct. 11th. Mr. Henry Lee had charge of the case. There was compound fracture of the leg, with unhealthy suppuration. The first rigor came on Nov. 1st, which was followed by profuse sweating and more rigors. The maximum temperature was 104; the respiration 58; and the pulse 164. Brandy and ammonia were prescribed. He died Nov. 4th. No post-mortem.

17. William L., a gardener, æt. 67, admitted under the care of Mr. Henry Lee Nov. 12th. He had been thrown in the street, and there was a scalp wound exposing the bone. The first rigor occurred on the 25th, and was followed by sweating and exhaustion. An attack of diffuse inflammation of the scalp preceded the pyæmia. Stimulants were administered, but he sank and died on the 1st of December. *Post-mortem.*—The wound was sloughy. The bone near the wound was infiltrated with pus. There was pus also between the bone and dura mater, and in the cavity of the arachnoid, with deposits in both lungs.

18.—Philip P., a groom, æt. 19, was admitted November 14th with a swelling on the right of the sternum, which had existed for some months. He was placed under the care of Mr. Tatum. The abscess was opened. On Nov. 21st, the first rigor set in, and was followed by repeated attacks, and sweating with dyspnœa. The maximum temperature was 103·2; the respiration 28, and the pulse 112. Bark, wine, and brandy were given. He lingered, and died Dec. 23rd. *Post-mortem.*—The first ribs at their junction with the sternum were carious, as were also the extremities of the clavicles, and upper part of the sternum. There was lymph over the left pleura, and an abscess in the right lung. The bodies of the first and second lumbar vertebræ were carious; and there was a large psoas abscess.

19.—William J., a cow-boy, 16 years of age, was admitted Nov. 25th under Mr. Holmes, with periostitis from a blow received six weeks previously. Dec. 3rd, the right shoulder had become painful and swollen, but he had no rigor. Effervescing salines, brandy, and morphia, were administered, but he died on the 6th. *Post-mortem.*—The right tibia was denuded of periosteum. Patches of intense congestion were found in both lungs, and abscesses in the left kidney. There was pus in the right knee, the left shoulder, and the elbow-joints.

20.—Thomas S., æt. 25, an engineer, was received Nov. 27th; Mr. Holmes attended him. He had been an out-patient with a crushed finger, which was amputated. He had rigors on both days before his admission, and several subsequently with sweating, cough, and purulent expectoration. The skin became jaundiced; he had bark, brandy, and ammonia ; he sank speedily, and died December 1st. *Post-mortem.*—The body was jaundiced, and covered with purpuric spots. Purulent fluid was found in the left pleura and pyæmic deposits in both lungs. The spleen was diffluent. The veins of the arm contained black fluid blood.

21.—William B., 14 years of age, an errand-boy, came into the hospital November 28th, and was attended by Mr. Pollock. For two years and a half he had lupus non excedens. Severe pain came on, December 27th, with swelling of the right knee, and was followed by swelling of the left knee and ankles. On January 11th there was great anxiety, and precordial pain with friction sound. He was supplied with stimulants, but died January 12th, 1867. *Post-mortem.*—There were secondary deposits in the right lung. Fluid was found in the pericardium, and the surface of the heart was covered with a layer of recent lymph. There was a secondary abscess in the spleen, and a large abscess in the recto-vesical fascia.

22.—Baldwin P., 14 years old, errand-boy, admitted and placed under the care of Mr. Henry Lee, Dec. 15th. He had an abscess of the thigh of nearly four months' standing. December 30th, cold night-sweats came on with hiccough and exhaustion. Stimulants were administered, but he died January 1st, 1867. *Post-mortem.*—Pyæmic deposits were found in the lungs, and amyloid deposit in the liver and kidneys. There was caries of the spine, and pus in the psoas muscle.

MERCER'S HOSPITAL.

PULSATING AORTA—EPIGASTRIC NEURALGIA WITH SPANÆMIA.

Under the care of Dr. MOORE.

(Reported by Mr. BACKHOUSE.)

MARY F., a pale, chlorotic, unmarried woman, aged 34, was admitted into the Hospital on the 14th October last. She complained of pain under the left breast, in the epigastric region, and along the course of the spine. She stated that occasionally she was tormented by a "throbbing" in her stomach, more especially before the menstrual periods. The menses were deficient in every respect. She had headache, flutterings, sighings, and was usually constipated ; she slept badly, had loss of appetite, and was much depressed. On a careful examination, there was no perceptible tumour in the epigastric region, but there was increased pulsation in the aorta, unattended with "bruit." The pain complained of in this region was periodic, occurring daily about the same hour. On inquiry, it transpired that she had reduced herself by extreme abstinence, (from religious motives), her principal diet having been strong tea.

She was ordered two grain doses of citrate of iron and quinine, with eight drops of tincture of digitalis in an ounce of infusion of columba, three times a-day. Soap liniment with chloroform was applied along the course of the spine; the bowels were kept free by a dinner pill ; her diet was milk, beef-tea, and wine. Under this treatment she left the hospital on the 12th November, greatly relieved.

Dr. Moore remarked that the symptoms in this case in some respects resembled those associated with abdominal aneurism. In the first place, the pulsation was high up, at the bifrucation of the diaphragm. Pain in the back was complained of, and violent neuralgic seizures, radiating backwards and upwards. On the other hand, there was

no bruit audible, and the neuralgic seizures were periodic, whilst the patient was spanæmic and the menstrual function was deficient. He regarded the pulsation as analogous to what is occasionally found in the thyroid body. No doubt the fact of the deep seat of the abdominal aorta rendered the diagnosis more difficult, but taking into account that the epigastrium is a frequent *locus* of pulsation and pain in females suffering from derangements of the menstrual function, he looked upon the symptoms in this case as functional.

Dr. Moore went on to say that the explanation of the epigastric pain, and pain in the region of the left breast, was a point of great interest. Sickness, headache flutterings, loss of appetite, &c., pointed to loss of nervous influence, more especially of the sympathetic system; and inasmuch as the epigastric region contained the greatest sympathetic plexus, the solar, with its offsets the semilunar ganglia, overlying the aorta and crura of the diaphragm, he thought the seat of the neuralgic pain could thus be satisfactorily accounted for. Again, the superficial and deep cardiac plexus, composed as they are of the sympathetic and cardiac branches of the vagus nerve (the latter believed by some to be also a nerve of the vaso-motor class), and occupying as they do the left mammary region, would rationally explain the pain in the left breast.

With respect to the treatment of such cases, Dr. Moore showed how futile it would be to endeavour to deal with the various symptoms which presented themselves. He advised them to change the character of the blood. This was best done by tonics and chalybeates, the menstrual and other functions gradually attaining a healthy condition, *pari passu*, with the improved condition of the circulating fluid.

WEDNESDAY, JANUARY 8, 1868.

UNIVERSITY REPRESENTATION.

The important considerations submitted to the St. Andrews Graduates by Dr. Sedgwick, and fully reported in our columns last week, deserve the attention of all University men, but more especially those of the, at present, un-enfranchised Universities. We have from time to time upheld the policy of increasing our University constituencies. We have urged that the University of London might well have been granted two members, and the offer of two between the four Scotch Universities was really niggardly.

But what can be said of the proposal to limit the right of voting to the residential graduates? Surely a more unjust and illiberal proposal was never made. What would be the result of it, if carried out at St. Andrews, has been shown on previous occasions in our pages, and the results of Dr. Sedgwick's investigations fully prove the truth of the statements we have made. We are sure that if only the matter be fully explained to Parliament, a close borough of the description proposed will not be allowed to be erected, but that each member of the University will be enfranchised. What could be more absurd than to give every artisan a vote for the constituency where he resides, but to deprive University graduates of their vote for *alma mater?* This is setting up wages with a vengeance, as the one qualification for political liberty. To enlarge the constituencies generally, but a side-wind—a parenthesis in a single clause—to hand over the representation of a learned body to a minority of its members is an outrage upon common sense which, we trust, the House of Commons will indignantly refuse to perpetrate.

We return to this subject, because it deeply affects the Medical Profession, and because we are too apt to be absorbed in practice, and neglect to lay claim to our rights. Medical men are never loud in their demands, and, in this age of struggling and noise, are apt to allow their rights or privileges, as well as their grievances, to remain unnoticed. It is time they woke up to a keener sense of them, and compelled the public to pass an opinion upon them. Another reason for our urgency in the matter is, that in this instance it is medical men who are exclusively affected. Graduates in Arts and Law of St. Andrews *are* resident, but not those in Medicine, because the old University has no Medical School. Seeking their knowledge elsewhere, those who resorted to St. Andrews for a degree, founded their claim to the distinction solely on their ability to pass the examinations. If residence be of such virtue, then the University of London must abandon its lofty pretensions, and acknowledge that, like its elder Scottish sister, it has no medical school of its own, no home in which to train the aspirants for its M.D., and that consequently for the future it must

"Hide its diminished head,"

and confess that the right to send a member to the great national debates was not deserved, but obtained through an oversight, if not even under false pretences.

Statesmen cannot afford to play fast and loose with principles. In a question like this, even Parliament which can, and does do many arbitrary and unreasonable things, will scarcely meet out one measure to London, but another north of the Tweed. The fact that the Scotch Reform Bill contained a provision for enfranchising the Universities, is a clear indication of this, and the injustice with which the medical Graduates of St. Andrews have been threatened will, we believe, be removed if they only take the pains to enlighten members of Parliament about it.

There is, however, no time to lose. The bill is gradually maturing, and the obnoxious clause may possibly again appear in it. The Association is probably still at work. It would be a great gain if the simple amendment, pointed out by Dr. Sedgwick, were to be adopted by the Government before the meeting of Parliament. This would save much trouble and annoyance, and only act justly by the large body of graduates. But if the Association cannot secure this, every individual Graduate throughout the kingdom should lay his case before the member for his county or borough, as well as before any M.P. to whom he can obtain access.

Such action would, we doubt not, combine the enlightened and liberal members of the House in one phalanx, determined to prevent the erection of a petty and untrustworthy constituency on the ruins of the hopes and rights of the Medical Graduates of the oldest Scotch University.

THE PROFESSION AND THE TOTAL ABSTINENCE MOVEMENT.

Mr. James Haughton, a gentleman well-known in Dublin as an ardent advocate of total abstinence, has published a communication addressed to the medical profession. We regret that we cannot transfer it to our columns in its entirety on account of its length. Mr. Haughton opens his remarks with a recapitulation of the evils which have accrued to society from the use of alcohol, and proceeds as follows :—

"The more the matter is inquired into, the more loudly is it sounded in our ears that to this cause is attributable nearly all our poverty, much more than one-half of our crime, and, at least, one-half of the madness which fills our lunatic asylums with their miserable inmates. Our poorhouses, our prisons, our lunatic asylums would be little needed but for our use of alcoholic liquors. Gentlemen, you may ask me why I address you specially on these questions? We are members, you may say, of the general community ; in what way are we peculiarly accountable to society for those evils you speak of, and which we admit have a real existence ; which we freely acknowledge do call for the serious consideration of every thoughtful, and especially of every educated person? But why are we appealed to more than others? Gentlemen, it is because I conceive that you do stand in a peculiarly responsible position in regard to this important subject that I now address you. Men listen to your advice on this subject. The use of alcohol affects health as well as morals, the latter I consider the far more important point ; but the former by no means to be neglected. But they hang closely together ; and you are responsible for the moral as well as the physical evils flowing from the use of alcoholic liquors, if you are, as I believe you are, too generally regardless of the light which science has, of late years, thrown on the deleterious effects produced by the common use of these baneful liquors by man in his normal or usual condition of health, and by your own use of them as a medicine in numberless cases where other medicines not dangerous to morals would prove quite as beneficial to your patients. This opinion I would not venture to give if I were not fortified in it by the writings and the practice of a large and a yearly increasing number of the most learned members of your body, both at home and abroad, who either protest against the use of alcohol as a medicine, or who recommend much more caution in its use than is still the general practice in the profession. It is sufficient to name such men as Bowman, Markham, Beale, Chambers, Smith, Carpenter, Lankester, Winslow, Monck, Adams, Buchanan, Gairdner, Nicolls, Mudge, Higginbotham, Munroe, Edmunds, Lallemande, Perrin, and Duroy—all men of standing in the profession, whose views on the subject fully justify the opinions long held by teetotallers, that the common use of alcoholic liquors is fatal to the health and happiness of man—that it contains no principle of nutrition, but that, on the contrary, it undermines the constitution, and makes all our diseases more fatal than they would otherwise be. Under all these circumstances, it will not appear strange to you that I, in the evening of my days, should address you specially in relation to your responsibilities regarding this great question, teetotalism. Your influence, as a body, is still cast in the scale against that principle. Through your means almost every family in these lands is impressed with the erroneous notion that the poison alcohol may be safely used. The physician is the friend and adviser in every household ; mothers have implicit reliance in your teachings. How necessary, then, is it to the peace, prosperity, and happiness of the community that your advice on this all-important subject should be guided by wisdom, and that you should clearly and strongly impress on every mind the great truth which science and experience alike enforce, that it is wrong to use alcohol in any form as a common beverage. I may be deemed a mere enthusiast for hoping that any considerable number of the learned body I now address will respond to my appeal. We have already the gratification to number in our ranks some of the most honoured members of your profession ; so that I cannot consider it a vain hope, for one who has served thirty years in this great work, who hopes he has secured the respect of some of you, and who himself has a high personal regard and respect for many of you, to entertain the idea, that some others among you, who have hitherto treated this great question too slightingly, may be induced to direct more of your thoughts to it. I shall only trouble you with one medical opinion, out of many which I could readily produce, as evidence of the propriety of my present appeal. Dr. Markham, late editor of the *British Medical Journal*, universally acknowledged to be well up in the medical literature of the day, says :—'Dr. Munroe, of Hull, has published a lecture 'On the Physiological Action of Alcohol,' and has adopted the uncompromising side of the anti-alcohol question. He goes in for the teetotal system ; and we feel bound to say, as the conclusion of the long discussion was published in this journal on the subject some time ago, that, on the face of it, teetotallers have, from a scientific point of view, the best of the argument. It is something refreshing, therefore, to meet with one who, like Dr. Munroe, practises what science seems to teach. The public, we think, are much indebted to him for making popular the physiological side of this question ; and if he be in error in his teetotal conclusions, he errs, at all events, on the safe side, and errs in accordance with the teachings of physiology, so far as they guide us in this case." I now leave the matter in your hands, and I pray that God may put it into the hearts of many of you to come out boldly in favour of teetotalism."

We cannot but commend the earnest and argumentative spirit in which Mr. Haughton's exhortation is conceived, and which is a favourable contrast to the wholesale and unmeaning denunciations indulged in by many disciples of total abstinence. Neither the profession nor the public will ever foreswear alcohol for mere vituperation, but a large section of them will undoubtedly do so, if it be proved that men of moderation and of astuteness, on whom they can depend, are on the side of total abstinence.

Notes on Current Topics.

The Public Health.

In the last week of the year 1867, the annual rate of mortality was 24 per 1000 in London, 30 in Edinburgh, and 22 in Dublin, 21 in Bristol, 29 in Birmingham, 32 in Liverpool, 32 in Manchester, 23 in Salford, 29 in Sheffield, 25 in Leeds, 26 in Hull, 27 in Newcastle-upon-Tyne, and 32 in Glasgow. In the whole of the towns together, the rate was 26 per 1000.

In London, during the week, the deaths registered were 1433. The average number of the fifty-second week of the year, corrected for increase of population, is 1595, so that the actual mortality was 162 less than usual. We thus find that the week was a very healthy one in London. The following particulars of the causes of death are selected from the returns :—

"Six hundred and eighty-two persons died under 20 years of age, 197 were 20 and under 40, 227 were 40 and under 60, 259 were 60 and under 80, and 68 were 80 years of age and upwards.

"Zymotic diseases destroyed the lives of 289 persons, 237 of whom were under 20 years of age. Whooping-cough was the most fatal disease in the zymotic class, and caused the deaths of 55 children ; 10 of these occurred in Kensington, 8 in Lambeth, 5 in Westminster, 3 in each of the districts of St. Luke and Bermondsey, and 26 in 20 other districts. Fifty deaths occurred from measles ; 10 in Newington, 6 in Kensington, 4 in Marylebone, and 3 in each of the districts of Clerkenwell, Bethnal-green, and Lambeth, and 21 in 17 other districts. Scarlatina caused 30 deaths ; 6 in Pancras, 5 in Lambeth, 3 in St. George, Hanover-square, 3 in Clerkenwell, and 13 in nine other districts. Seventeen deaths from smallpox, 12 from diphtheria, 52 from typhus, and 11 from diarrhœa were registered in the week.

"From diseases of the respiratory organs (exclusive of phthisis) 345 persons died ; of this number bronchitis carried of 202, pneumonia 86, and asthma 18 persons.

"One hundred and sixty-four persons died last week from phthisis, 72 from diseases of the heart, and 129 from diseases of the brain and nervous system."

THE PAST YEAR.

As the returns are now completed for the year 1867, it may be well to add to the above items a few particulars as to the whole year, the varying state of which it has been our duty to chronicle from week to week :—

"The annual rates of mortality, per 1000 persons living, in the great cities of the United Kingdom during the year 1867, arranged in order from the lowest, are as follow :— In London 23, Bristol 23, Birmingham 24, Sheffield 25, Hull 25, Leeds 27, Edinburgh 27, Dublin 27, Salford 29, Glasgow 29, Liverpool 30, Manchester 31, Newcastle-on-Tyne 31. The mortality showed a decrease in nearly all the towns upon the rates which prevailed in 1866. Among those towns which did not suffer from the cholera epidemic last year, the improvement was most marked in the borough of Leeds.

"In London during the 52 weeks comprised in the returns of the present year, the births have been 112,264, and the deaths 70,588. The births in the year 1866 were 107,992, and the deaths 80,129.

THE statistics of the large towns of the Kingdom for whole years are now ready in a form available for comparing them for the three years last past. It appears that the annual rate of mortality for the years 1865, 1866, and 1867 respectively was per 1000 persons living as follows :—

Birmingham, 25, 24, and 24 ; the density of population (persons to an acre) in 1867 was 44. Hull, 27, 24, and 25; density, 30. Bristol, 24, 25, and 23 ; density, 35. Edinburgh, 28, 27, and 27 ; density, 40. Dublin, 26, 28, and 27 ; density, 33. Salford, 29, 29, and 29 ; density, 22. Glasgow, 33, 30, and 29 ; density, 87. Manchester, 33, 32, and 31 ; density, 81. Leeds, 31, 33, and 27 ; density, 11. Liverpool, 36, 42, and 30 ; density, 96. A great reduction in the death-rate of Liverpool may be observed since a large sum of money was expended on sanitary improvements. Many houses have been demolished, middens have been emptied or removed, and the ventilation of the sewers has diminished fever. The annual mortality in Sheffield in each of the years 1866 and 1867 was 28 and 25 ; density, 10. In Newcastle-on-Tyne the annual mortality in 1866 and 1867 respectively was 32 and 31. The results for London in each of the three years 1865-7 respectively were, annual mortality per 1000 of population, 25, 26, and 23; density, 40. It may here be noticed that Bristol, Leeds, and Liverpool, have each a medical health officer. Birmingham, Hull, Salford, Manchester, Sheffield, and Newcastle-on-Tyne have no medical health officer, but most of these towns, however, have introduced some sanitary improvements. London has 47 health officers, all of whom have devoted much time and attention to their offices.

Drainage.

A FEW months ago we gave an account of Mr. Child's statements respecting the plan of drainage adopted by the authorities at Milan. He again brings the subject forward, and seems to regard this plan, which has stood the test of ten years' trial for a city of 200,000 inhabitants, as suitable for adoption by the towns of the Thames valley, which are now at their wit's-ends for a mode of disposing of their sewage. An estimate of £54,000 for draining Oxford has been submitted, and this would impose an expense, in proportion to the inhabitants, of some 35 per cent. more than the main drainage scheme has cost Londoners. Mr. Child believes that £5000 would give the Milan plan a trial in a town of moderate size, and he is desirous that the Government should lend the money to some town willing to make the experiment.

It is quite clear that the great questions of drainage grow rapidly in importance and tend to enforce themselves upon us in a most unpleasant manner. The towns that have had to try to solve the problems of the age are constantly increased ; and, in relation to the public health, medical men must continually pay attention to such matters.

Royal College of Physicians of London.

THE Gulstonian, Croonian, and Lumleian Lectures for this year will be delivered by Dr. John Harley, Dr. Bence Jones, and Dr. Guy. They will, no doubt, attract a select audience, and prove as valuable as those of other years.

We are informed that the arrangements of this College are now complete for the granting of a double diploma in connection with the College of Surgeons, but the authorities of Lincoln's-inn are said to be still busy preparing a report. We presume that some day this great step will be really accomplished, and that the two Colleges will be actually seen working together; but he would be a bold prophet who would venture to say *when* this shall be brought about.

King's College School.

ON the 31st ult. a dinner of the old pupils of this school was held in the hall. The Rev. F. J. Manning, D.D., said to be the first pupil who entered the school, occupied the chair. A proposal was made at the dinner to found a scholarship, which we hear is likely to be carried out.

Technical Instruction.

BY a minute lately passed, important facilities for scientific education have been afforded to elementary schools, whether aided by the State or not. The plan is to assist local efforts to establish scholarships and exhibitions. These are to be awarded by competition to the most successful students, according to the conditions imposed by the Committee of Privy Council.

These privileges are to be restricted to artisans or poor students of from 12 to 16 years of age.

A Rare Plant.

THERE may now be seen in the Royal Botanic Gardens, Regent's Park, a very rare kind of agave in flower. It is believed by many to be the first of the kind that has ever flowered in this country. The flower spike is some ten feet long, the point nearly touching the ground. The specimen was raised from seeds obtained from Mexico, and planted in the Botanic Gardens about 25 years since. It is labelled *Agave dasylirioides*, but many of the visitors seem inclined to take exception to the name, and point out how much it differs from other sorts of agave.

The Vaccination Returns.

ABSTRACTS have been published of returns from the parishes of Scotland, respecting the Act to "extend and make compulsory the practice of vaccination in Scotland." During the first half of last year there were 2072 successful, and 72 unsuccessful cases. Twenty-two certificates were granted that the patient was not susceptible to the virus. There were also 204 cases in which vaccination was performed ineffectually on account of the patient having been successfully vaccinated on a previous occasion. There were 1221 persons not in receipt of parish relief vaccinated.

Further, there seem to have been 4679 defaulters under the 18th section of the Act. There were only four prosecutions under the 25th section, and of these only two resulted in conviction and penalty.

We are informed that the new provisions for the supply of lymph, have been successful.

A New Sanitary Journal.

THE growing importance of the study of hygiene, and the new-born interest which has attached to it of late, have given birth to a new periodical, the *Public Health*, which has just issued its first number, and will appear monthly if it shall receive a fair amount of public support. We learn that it is under the direction of Dr. Hardwicke, Medical Officer of Health for Paddington; Deputy Coroner for the City of London, and Secretary to the Health Section of the Social Science Association. We wish the venture every success, for there is undoubtedly a place for it as a chronicle of important matters which could not find a suitable place either in the medical or general press.

The Sources of Tropical Fevers.

DR. BOSE, the native lecturer in anatomy in the Bengal Medical College, has communicated some very important researches on the origin of epidemic fevers in India. He attributes these outbreaks in most cases to the disturbance, in the execution of public works, such as digging of tanks and making of roads and railways, of the soil which has been charged with miasmata by inundations and destructive tornadoes. He traces the occurrence of many of these epidemics to the influence of an inundation about fourteen years ago, which, he says, has, by its effects on the soil ever since, given birth to malaria whenever the strata were disturbed; and he anticipates similar results from the cyclone of 1864. Dr. Bose's researches are corroborated very closely by the circumstances of the late epidemic at the Mauritius, which we pointed out as having occurred under precisely similar conditions.

Contagious Diseases in Ireland.

WE learn that the office of Local Secretary for Dublin to the Association for the Extension of the Contagious Diseases Act to the civil population, has been accepted by Dr. Hamilton Labatt. Dr. Labatt is the author of a well-known memoir on syphilis, and is a Member of the Council of the Royal College of Surgeons in Ireland. There is, probably, not a city in Europe so peculiarly situated as Dublin, in respect of the matter to which Mr. Labatt has to apply himself, and the task of investigation will be no easy one. The characteristic chastity of the Irish female population, their greatest virtue, renders clandestine immorality comparatively very unfrequent, and, as a natural sequence, aggravates, in a marked degree, the "social evil." In a strength of 750 men, the 74th Highlanders has, in one week lately, sent twenty-two men to hospital for venereal diseases, a proportion equal, if it were mentioned, to nearly 150 per cent. of the entire force invalided from this cause in the year.

Prescribers v. Dispensers.

THE Apothecaries of Philadelphia have drawn out on themselves great discontent on the part of the profession there, and an intestine war has sprung up, which has led to many recriminations.

The physicians accuse the Dispensers *inter alia* of appropriating prescriptions confided to them, and advertising them for sale to the general public as their own—of combining the sale of pens and ink, lollypops, soap, and tipple, with the dispensing of medicines, and, at the same time, advising and prescribing as regular medical practitioners.

These are serious charges, and offensive to our ideas of propriety. Are we quite sure that a certain class of general practitioners in Great Britain are clear of such practices?

DR. GEORGE HARDY, F.R.S., has recovered from the illness which has so long been a source of deep sympathy with a large portion of the Profession in London, and is able to resume his professional work.

THE death of Mr. Teale, of Leeds, although at the age of 67, seems to have produced a widespread feeling of loss and regret. His name has long been in the front rank of Surgeons, and his private character had endeared him to a large circle of friends.

THERE is a talk of the London College of Surgeons appointing authorities in biological science to assist at the examinations. Some people believe that this will actually be done. If it should be, nothing can surprise the Profession afterwards.

DR. DRUITT has resigned the office of Medical Officer of Health for the district of St. George, Hanover-square.

THE authorities of St. Mary's Hospital Medical School have advertised a vacancy in the chair of Pathology, with which is combined the curatorship of the museum.

THE Chair of Physiology at Charing-cross Hospital is also vacant.

THOSE who have been so much interested in the health of the Princess of Wales, will be glad to hear that H.R.H. attended church at Sandringham on Christmas morning.

THE accident to Mr. Gladstone, of which some of the papers made so much, was of a trifling nature. It is true that a splinter struck the eye of the right hon. gentleman, while he was watching the felling of his trees, but the injury it inflicted was slight, and the sight at no time in peril.

THE daughter of the late Dr. Southwood Smith, is to receive a small pension from the civil list.

WE extract the following from the (Official) *London Gazette* of Tuesday:—"The Queen has been pleased to appoint Mr. Peter Wyatt Squire, to be chemist and druggist upon the establishment in ordinary to Her Majesty, jointly with his father, Mr. Peter Squire."

Upon reference to the back volumes of *The Gazette*, we find Mr. Squire, sen., obtained the appointment with the medical staff about thirty years since. The official announcement is dated August 8, 1837. Mr. Squire is the author of "The Companion to the British Pharmacopœia," a work in great repute with the profession.

DECEMBER, 1867.

THE past month has been a very remarkable one—characterised by constant and violent oscillations of temperature and other unusual weather manifestations. Mr. R. H. Allnatt, of Frant, thus sums up the meteorology of the month:—

"On the 1st, during the tempestuous gale, the morning temperature was 53 deg., and the night 38 deg.; six deg. above the freezing point of Fahrenheit. The following morning a depression took place of 13 deg. morning temperature and 12 deg. night. A rise then occurred of 4 deg. mean temperature, and up to the 9th it fluctuated between 30 and 33 deg., when

it again sank 5 deg. During the night of the 9th and morning of the 10th the cold was excessive, and the minimum thermometer indicated 11 clear degrees of frost, the sky became overcast with cloud and mist, and atmospheric saturation resulted. On the following morning the temperature at 10 A.M. had risen 6 deg., and produced a rapid thaw. On the 11th the temperature had risen to 45 deg., 10 deg. above that of the preceding day. On the 12th night and morning temperature attained respectively 44 and 53 deg., a rise of 10 deg., and continued above freezing till the 19th, when it again sank to a mean of 32·5 deg., and on the following day became still more depressed. It then fluctuated between 41 and 38 deg. until the 29th, when it fell, and the mean to the end of the month was 1·6 deg. below freezing.

"There were 16 hard frosts during December, the combined action of which, according to calculations from aggregate temperature below 32 deg., or the freezing point of Fahrenheit, was 81·5 deg., thus making the mean of each night about 6 deg. of clear frost. The mean of night temperature above the freezing point on the remaining nights amounted to nearly 7·5 deg. So that the average temperature of the month was on the whole rather above than below the standard. Atmospheric pressure, except on the 1st, during the period of the great gale, was persistently steady, and ranged below an inch. Snow, hail, sleet, or rainfall occurred on 12 days, and in combination gauged 2·67in., which is above the estimated average. Ozone was abundant, and considerably exceeded the mean of the season. It attained its maximum on ten days. On the 19th there was no perceptible action on the newly-exposed test, but it was not a period of antozone, inasmuch as that the coloured slip was also unaffected. On the 20th, however, a full-coloured ozonoscope, which hung by the side of a virgin test, owing to the antagonistic action of antozone, was deprived of upwards of 8 deg. of its purple hue. In the afternoon the slips showed signs of reaction, and at 2 P.M. of the 21st, the wind blowing S., the ozonoscopes attained their full development. Atmospheric saturation occurred on the 1st, 5th, 10th, 11th, and 29th, and the psychrometic range was from 80 to 100. Some latitude, however, may be given to the literal accuracy of these readings, as during the late frosts evaporation from the wet bulb has necessarily proceeded very languidly."

Foreign Medical Literature.

CASE OF MULTIPLE STRICTURES IN THE SMALL INTESTINES.

COMMUNICATED BY PROFESSORS MALMSTEN AND KEY.

Translated from the *Hygiea* for July, 1867, p. 300,

By W. D. MOORE, M.D., Dub. & Cantab., M.R.I.A., L.K.Q.C.P.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS; THE NORWEGIAN MEDICAL SOCIETY; AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; SECRETARY FOR SWEDEN, NORWAY, AND DENMARK, TO THE EPIDEMIOLOGICAL SOCIETY OF LONDON.

W——, a divorcée, aged 33, was admitted into the medical clinique of the Seraphim Hospital, from Stockholm, on the 24th February, 1867.

Status antecedens.—Both her parents are dead, but the patient is unable to say of what disease they died. Neither of them, however, nor any other of her relatives, ever suffered from phthisis, or from any serious abdominal affection. She, herself, as a child was healthy, except that she often passed lumbrici in considerable quantity. At 20 she married and passed through two confinements, the latter of which, nine years ago, was particularly severe. She nursed her last child for eleven months, and did not remark her strength giving way to any considerable extent. But three years after her last confinement, she miscarried in the second or third month, as she herself believes, in consequence of over effort in lifting a bath-tub. On this occasion she lost much blood, kept her bed for three months, and has never since regained her former strength. From this time she has complained of dyspeptic derangements, consisting in pain and griping in the abdomen, but since about seven ells of tape-worm have come away, these symptoms diminished, though, on the other hand, she began to emaciate, felt a gradually increasing languor, so that she was tired on the slightest exertion; her spirits became depressed; she was easily set crying, and often suffered from headache; her appetite was, at first, tolerably good, but gradually fell off; menstruation, which had before been regular, ceased two years ago. Her hygienic circumstances, which had previously been good, having in the interval become unfavourable, the latter years having been particularly unfortunate for her, the symptoms just described became aggravated, and she began to be occasionally troubled with a loud, hoarse cough, at first dry, but during the last six months accompanied with scanty expectoration, occasionally streaked with blood. About a year ago she began to be troubled with fulness and spasms in the abdomen, with nausea and occasional vomiting. The latter has usually followed the use of food, which she has borne only in the liquid form (chiefly beef-tea, but not milk). The vomiting itself was not attended with pain, but during the time (from one to three-quarters of an hour) which elapsed between the ingestion of food and the vomiting, the patient sometimes, but not always, had severe cardialgic pains, radiating from the epigastrium to the back and sides. The vomited matter consisted of mucus and undigested food, but she denies having found any blood in it. At the same time, she began to suffer from diarrhœa, recurring five or six times in the day. The motions were never bloody, and were not accompanied with tenesmus. She was admitted into the dispensary hospital in the end of September, and was discharged, at her own request, in the beginning of November. During that time she was treated with oily emulsion, hydrocyanic emulsion, and iron with bicarbonate of soda. After her discharge from hospital, her state became worse, the vomiting, diarrhœa, and abdominal pains returned. She had occasional night sweats. Once or twice there was slight jaundice, which soon disappeared. She has latterly been confined to bed, and shortly before Christmas she observed a swelling in her legs, which, however, again disappeared after about a fortnight's rest in bed. She has sometimes even observed that her face was swollen. For some days before her admission, the motions, which varied from four to six in the day, were occasionally attended with griping. After her admission, she had an anodyne stupe; on the 25th, oily emulsion; on the 26th, an emulsion of myrrh and iron; and on the 27th, a sinapism to the abdomen.

Status præsens, 27th February.—The patient is of middle size, very thin. She is extremely weak, but is quite clear in her intellect. She had some sleep during the last few nights, without perspiration. Her temperature is 99·6° F. Her skin feels dry.

The sound on percussion over the greater part of the front of the chest is full and clear, without any perceptible difference between the two sides. On the right side, dulness commences at the fifth intercostal space, and extends three inches downwards. Pectoral fremitus is tolerably strong over the front of the chest. The respiration is superficial, vesicular with mingled mucous râles. There is not very much cough. The expectoration contains air; no elastic filaments can be discovered in it. The cardiac dulness commences in the fourth intercostal space, and extends 2 inches downwards, and about 1½ inches outwards from the edge of the sternum. The impulse is felt in the usual situation. The sounds of the heart are weak, without any accessory murmur. The action of the heart is considerably increased on the least exertion. The pulse is small, about 100. Anæmic murmurs in the cervical vessels.

The abdomen is somewhat swollen, very tender on pressure, especially in the epigastric region, it yields throughout a normal sound on percussion. Gargouillement is perceptible on palpation. No tumour or inequality can be discovered, there is no dropsical effusion. The patient has, for the last few days, not vomited more than twice daily. The vomited matters were not bloody, and consisted chiefly of mucus. The abdominal pains have greatly teased the patient, who states that they now occur at other times than after food has been taken. She has no appetite, but great thirst. She had a tolerably loose motion last night, without blood or griping.

The urine, which the patient thinks increased in quantity during the last week, is rather dark-coloured; its specific gravity is 1·017, it is free from albumen.

28th.—The pain and tenderness in the abdomen have increased, and extend principally to the right side. The patient has great difficulty in drawing her breath; she has had no vomiting, nor any action of the bowels since yesterday. Her sleep during the night was disturbed. Ordered to be kept quiet, and to get morphia and bi-carbonate of soda.

Same day, evening.—The patient is now less sensitive to pressure, complains of pain in the right side. The dulness on percussion begins on the right side at the fifth rib, above that, the sound on percussion is clear, and the vibrations of the voice are distinct. In the right lateral region the vibrations of

the voice seem inferiorly to be weaker than in the corresponding part of the right (sic) side. But on account of the abdominal pains and the patient's extremely weak condition, a complete examination of the chest cannot be made. The respiration is extremely superficial and rapid. The respiratory murmur over the front of the chest is indistinct, over the right lung scarcely any respiration is heard; over the left some feeble râles are audible. There is great dyspnœa. The cough is inconsiderable, without expectoration. The pulse is small, about 120. The urine, the specific gravity of which is 1·016, is free from albumen, and contains but a small amount of chlorides.

March 1.—During the night, the patient had a couple of hours disturbed sleep. Her state was in other respects unchanged. She had neither vomiting nor discharge from the bowels since 28th February.

2nd.—The sound on percussion over the front of the right side is somewhat duller than on the left side. The pectoral fremitus is weak, but distinct over the front of both lungs. Respiration continues as before. The tenderness and the pains in the abdominal region are likewise rather diminished over the right side. Dyspnœa.

3rd.—During yesterday, the patient lay for the most part in an occasionally interrupted stupor, without complaining of any severe pains. She died quietly to-day at 10.30 A.M.

The changes found at the post-mortem examination on the 7th of March were described by Hr. Key, as follows:—

The body was apparently slight, though it presented a tolerably thick panniculus adiposus over the abdomen. Faint but extensive lividity on the posterior surface of the body. The skin over the abdomen presents a greenish yellow discolouration. There is no cadaveric rigidity. The muscles are particularly pale. The right lung, which collapses imperfectly, pushes the heart somewhat over to the left. The right pleura contained about twenty-five ounces of straw-coloured fluid, with numerous fibrinous flocculi. Over the entire of the lower lobe, as well as over the posterior part of the superior, the pleura is dry, dull, and (particularly on the posterior part of the lower lobe) covered with a yellowish grey, rather thin, fibrinous layer, adhering more or less firmly to the surface of the pleura. On a surface the size of a hen's egg posteriorly at the lower margin of the inferior lobe are numerous ramified, yellowish grey striæ, which, in some places, exhibit ampullular dilatations, and seem to be embolised lymphatic vessels. With the exception of a small, soft atelectatic focus in the infero-posterior margin, the pulmonary substance is in the back part of the whole of the lower lobe more resistant than usual, with a dry, reddish grey, finely granular surface of section, nowhere crepitating, considerably more brittle than is normally the case, and on strong pressure, yielding a pultaceous mass. In the anterior half of the lower lobe the parenchyma is soft, skin-like to the touch, only slightly crepitating, its surface of section is smooth, of a bluish red colour, yielding on pressure a somewhat turbid, but slightly frothy fluid, in not very abundant quantity. The middle lobe is throughout pale, tolerably dry, and entirely permeable to air. The upper lobe is, for the most part, of the same nature as the middle, but in the posterior fourth it is almost atelectatic, with soft but strong, not crepitating parenchyma, and a livid surface of section, from which on pressure a small quantity of not frothy fluid exudes. About in the middle of the upper lobe, the parenchyma surrounding a medium-sized bronchus is in a focus of the extent of a walnut sclerotic, of a whitish grey, in spots highly coloured. Here and there, in this focus, are seen small, more purely white, points; in the centre of the part too, a small caseous focus was found. This was ascertained on closer investigation to be a bronchus, whose calibre was filled with the caseous mass. The white points appearing in the sclerotic focus seem to be small, thickened bronchi, whose calibres are here and there distinctly perceptible. The bronchial glands are deeply coloured, and are tolerably large, with caseous metamorphosis in a couple of smaller foci. The left lung is throughout its entire extent attached to the thoracic wall by means of particularly firm adhesions of connective tissue. In the posterior parts of the upper, and in almost the whole of the lower lobe, the lung is considerably more resistant than is normally the case. On cutting through the lower lobe the latter crepitates only in the anterior margin, and exhibits in general a rather highly speckled surface of section. From the posterior edge it is, for the extent of half an inch inwards, of a dark livid appearance, and the parenchyma is here soft, yielding on pressure a small quantity of blood-coloured fluid (atelectasis). Strings of the same nature, varying in width, are continued within the lobe, which otherwise, with the exception of the permeable anterior margin, is of a greyish red colour, with a finely granular surface of section. The parenchyma is here brittle, and easily breaks up into a pulpy mass. The upper lobe is posteriorly highly œdematous, in the anterior portions it is otherwise normal, but with a slight thickening of the connective tissue around the vessels and bronchi; there is no sign of circumscribed foci or tubercles.

The heart is small, containing in both sides some firm fibrinous coagula. The muscular structure of both ventricular walls is rather thin, with a brownish grey tint. the wall of the right ventricle is moreover in its superficial layer traversed by yellow striæ. The endocardium in the left ventricle is whitish grey, and is more opaque than usual. The valves of the aorta, as well as both lobes of the mitral valve, are slightly thickened, but without retraction.

On opening the abdominal cavity no effusion is met with, nor any extensive peritonitis. The stomach is rather highly distended, and is of old attached by a couple of fine, whitish grey, firm adhesions to the under surface of the liver. Twelve inches below the duodenum, and thence down to the valvula coli, are seen in the small intestine a number of cicatrix-like contractions, placed at different distances, some only a couple of inches from one another. In many places they resemble cicatrices with strictures after the healing of intussusceptions. Thus one piece of intestine seems with rapid diminution to project, as it were, somewhat into the other, while the peritoneum is greatly thickened about the contracted parts. From the peritoneum thickened at the contractions, more or less numerous fimbriæ of connective tissue project, of which some are livid, in consequence of great sanguineous congestion in their elongated vessels, which densely traverse the fimbriæ. The peritoneum itself is likewise strongly injected, both in the seats of contraction themselves and in their immediate vicinity. The mucous membrane of the stomach is particularly pale, in the antrum pylori exhibiting a number of closely placed, small, low, granular elevations, but otherwise it is not thickened. In the lesser curvature and the greater part of the saccus cæcus is a superficial gastro-malacic dissolution of the mucous membrane. The muscular coat is not thickened, not even at the pylorus.

The mucous membrane of the duodenum is in general rather thick and softened, on the lower half it assumes a slate-grey colour, exhibiting a number of small, black points, depending on deposition of pigment in the apices of the villi. In the first cicatrix-like contraction of the jejunum, rather more than 24 inches below the stomach, there is found in the mucous membrane a cicatrix 1½ centimètres in breadth, which from the mesenteric attachment runs up towards the free margin of the intestine, leaving there only a slight bridge of mucous membrane untouched. Around the cicatrix the uneven contracted margins of mucous membrane are intimately adherent to the cicatricial tissue itself, which consists of a tolerably smooth, slate-grey, firm, tense, connective tissue. Nowhere is there any trace of tubercles. The next two strictures, which are situated at nine inches distance from each other, are so considerable that their calibres scarcely admit the introduction of an ordinary pencil. They were not slit up, in order not to injure the preparation. The cicatrices found lower down in the intestine, at a greater or less distance, at each stricture, exhibited in general precisely the same characteristics as those above described. Some of them went quite circularly round the whole intestine, others in a longitudinal direction, some were quite small and rounded. All were healed and very tense, only in some few were slight losses of substance seen, caused by recent ulceration. In none were tubercles found, nor could any such be discovered in the thickened and injected peritoneal investments corresponding to the cicatrices. Down in the ileum the strictures and cicatrices lay much closer than in the jejunum, and the last two inches of the ileum consisted of a single cicatrix. The mucous membrane of the large intestine was pale, thin, without a trace of any morbid process.

The spleen was particularly small, adherent to the diaphragm by old and firm false membranes. In consistence it was firm, with smooth, reddish grey surface of section. The vascular walls were thick; the trabecular system was highly developed, the Malpighian bodies were small.

The left kidney exhibits on its surface rather well-marked fœtal lobulation; it is to the touch rather firmer than usual, the capsule is slightly thickened with increased adherence. The stellulæ Ferreinii are rather more than usually developed. The surface of section is particularly smooth, shining, with a sharp edge.

The pelvis is of a pale, greyish white. The Malpighian bodies project as red points. The pyramids likewise are pale, here and there with rather yellow-streaked papillæ. The right kidney very strongly resembles the left. The upper surface of the right lobe of the liver is adherent by means of some small, firm, particularly thin false membranes to the diaphragm, as the under surface of the left lobe is to the stomach, as above remarked. The liver is particularly thick and plump, soft and doughy to the touch. The surface of section is remarkably dry, of a pale yellowish grey, leaving an abundant coating of fat on the knife. Acini, of the normal size, exhibit in their centres a somewhat depressed, brownish red point, while they are otherwise throughout of an uniformly yellowish grey colour. The substance of the liver is more brittle than usual.

Hr. Key's view of the case was as follows :—

Undoubtedly, the above instance of such extremely numerous and considerable strictures in the small intestines is unusual, and, for my own part, I have never seen anything comparable to it, nor can I recollect to have seen anything like it described. And these strictures have, moreover, been developed in such a latent manner, that they could scarcely be suspected by anyone during life, as the symptoms connected with the digestive organs might easily be explained in another mode. The first question to be answered is this :—Of what nature are the cicatricial formations in the tumour? On what process do they depend? And the second question is: When did this process begin? As to the nature of the cicatricial formations, it cannot be denied that at first sight there seems to be much in favour of their tubercular character. Their distribution in the intestine, their tendency in general to spread circularly, their marked proliferations of a tense connective tissue in their fundi and edges, the considerable reaction in the peritoneum over the fundi of the ulcers, would all mark the latter as tubercular. But against such an interpretation we have, on the other hand, the very strong testimony of the fact, that all the ulcers were perfectly healed, with the exception of some small fresh ulcerations in the cicatrices themselves. Moreover, nowhere in the cicatrices, in their surroundings, in the thickened peritoneum external to them, or elsewhere in the intestine, could any tubercles be discovered. If the cicatrices were the results of tubercular ulcers, we should here have before us a case, where the most intense tubercular process in the intestine finally ceased, leaving behind it completely cleansed and cicatrising sores. That tubercular sores may partially—nay, that isolated ulcers may, in such a manner, be entirely healed is well-known ; but that such a process, presenting the intensity which here existed, should altogether cease, is by no means admissible. Besides, no tubercles were met with in any other organ. The sclerotic focus in the centre of the upper lobe of the right lung, which fully explains the woman's hacking cough, &c., was evidently dependant on a chronic peribronchitis and interstitial pneumonia, and no tubercles were discoverable in either lung.

That the cicatrices should be the results of typhous ulcers cannot be admitted—not merely because the woman, according to the report of her case, never had any typhoid fever, but principally because the whole cicatricial formation in the above description, is so unlike that which takes place in typhous ulcers—which, in consequence of the slight formation of connective tissue in their fundi, extremely rarely, if ever, form strictures by continuous cicatrices.

It remains for us, therefore, only to assume that a chronic follicular enteritis was the process, which laid the foundation of the extensive formation of ulcers and cicatrices ; and there is nothing in the nature of the latter inconsistent with this assumption. That such considerable strictures, however, should have arisen in so many places as results of such a process, is in the foregoing case worthy of attention, equally with the insidious course of the process, and the resemblance of the symptoms to those accompanying constriction of the pyloric region of the stomach. One could scarcely have, during life, diagnosed the situation of the strictures, or suspected such serious changes in the small intestines, while the stomach was so little affected. As to the date of the setting in of the process, there is no reason for putting it farther back than about a year, when the woman, as the Journal shows, began to suffer from diarrhœa, with other severe derangements of the digestive functions.

EXTRACT OF MEAT FOR ABYSSINIA.—The Government has contracted with Liebig's Company for a supply of their "extract" for the troops. Each soldier will be provided with a number of small jars, which can be easily carried.

Medical News.

OXFORD, DEC. 31.—The Examiners for the Radcliffe Travelling Fellowship, Dr. Acland, Dr. Rolleston, and Sir B. C. Brodie, have given notice that the next examination will commence on Monday, February 3, at 10 A.M., in the Museum. Candidates are requested to forward notice immediately to Dr. Acland of their intention to present themselves.

NEW VACCINATION ACT.—The Act passed on the 12th of August last to Consolidate and Amend the Laws relating to Vaccination in England, and of which we long since gave an elaborate abstract, came into force on the first day of the year, and we are therefore now called upon to carry it out. With the exception as to the divisions and districts of unions and parishes previously made, and to all contracts made and not completed, and also as to liabilities and responsibilities incurred, the Acts and parts of the Acts named are repealed on and after the 1st of January, 1868. The guardians of unions and parishes, where the same have not been divided into districts for the purpose of vaccination, may form districts and consolidate or alter the same, subject to the approval of the Poor-law Board. When a scheme is approved the guardians may enter into a contract with a duly registered medical practitioner for the performance of vaccination of all persons resident within such district, and he is to be termed the public vaccinator, and when the existing contracts terminate the guardians are to enter into others with such modifications as the circumstances render necessary, subject to the approval of the Poor-law Board. The qualifications of vaccinators are to be prescribed by the Lords of the Privy Council and regulations to be made. The Privy Council may, in addition to the payments made by guardians to the vaccinators, allow one shilling for each child whom the vaccinator has successfully vaccinated. The fee to be paid by guardians is not to be less than 1s. 6d. in each case for a successful performance within a mile, and 2s. over one mile and under two, and 3s. for every vaccination done at any station over two miles' distance from his residence. Provision is to be made in the contracts as to conditions and as to re-vaccination. No contract as to vaccination is to be valid unless approved by the Poor-law Board, and the board is empowered to determine the same at any time. No payment is to be made out of the poor-rate unless the Poor-law Board have approved the contract, and no public vaccinator is to be paid for vaccination out of his district. In places where the population is scanty, arrangements may be made for the attendance of a public vaccinator at intervals of three months. The Registrar-General is to provide forms. On a child being registered, or within seven days, the registrar is to give to the parent or other person a notice to have the child vaccinated within three months, and in the following week after the operation the child is to be taken to the vaccinator for inspection. Certificates of successful vaccination are to be transmitted to the registrar, and a duplicate given to the parent; and where vaccination has been performed by a medical practitioner, not being a public vaccinator, a certificate is to be forwarded to the registrar of the district. The registrar is to be paid fees by the guardians. There is an express declaration in the Act, that vaccination is not parochial relief. Every parent or person neglecting to procure the vaccination of a child or causing the same to be inspected, to be liable to a penalty, on summary proceedings, of 20s. Justices may make an order for the vaccination of a child under 14, and in default impose a penalty of 20s. Costs, &c., may be awarded on a person being improperly summoned. Inoculation for the small-pox with variolous matter is to be deemed an offence, rendering the operator liable to one month's imprisonment.

DEATH OF PROFESSOR MACDOUGALL.—We regret to announce the death of this gentleman, who has been for some time in a state of impaired health, and who this session was unfortunately unable to resume his usual duties at the University of Edinburgh. Since the commencement of the present session the Moral Philosophy class has, with the sanction of the Senatus, been taught by Professor Fraser. The late Professor Macdougall was for a good many years teacher of moral philosophy in the Free Church College, and in 1852, on the demise of the eminent Professor Wilson, he was chosen to succeed him as Professor of Moral Philosophy and Political Economy.—*Edinburgh Courant.*

DEATH OF MR. T. P. TEALE.—The *Times* of Jan. 1 thus records the decease of Mr. Teale:—"Mr. Thomas Pridgin Teale, an eminent consulting surgeon at Leeds, died at his residence at that town yesterday, aged 67, within one day. The deceased held high rank in his profession, being one of the Medical Council, and also one of the Royal Medical Commissioners. He was likewise a Fellow of the Royal Society. His illness had only been of short duration, and his death was somewhat unexpected."

LIST OF MEDICAL PUBLICATIONS.

Baird (James) Management of Health: a Manual of Home and Personal Hygiene: being Practical Hints on Air, Light, and Ventilation; Exercise, Diet, and Clothing; Rest, Sleep, and Mental Discipline; Bathing and Therapeutics. (Weale's Rud. Ser. 112.) 12mo, cl. sd. xi—108. Virtue.

Braithwaite's Retrospect of Medicine: being a Half-Yearly Journal, containing a Retrospective View of every Discovery and Practical Improvement in the Medical Sciences. Vol. 56. July—Dec., 1867. post 8vo, pp. xlviii—407. Simpkin.

Dickinson (William H., M.D.) On the Pathology and Treatment of Albuminuria. 8vo, pp. xxiii—265. Longmans.

Dewar (James) On the Application of Sulphurous Acid Gas to the Prevention, Limitation, and Cure of Contagious Diseases. With Cases illustrative of the Advantages to be derived from its Employment. 2nd edit. 8vo, sd., pp. 61. Edmonston.

Fergusson (Sir William) Lectures on the Progress of Anatomy and Surgery during the Present Century. 8vo, pp. xi.—302. Churchill.

Fox (Wilson, M.D.) On the Diagnosis and Treatment of the Varieties of Dyspepsia, considered in relation to the Pathological Origin of the different forms of Indigestion. 2nd ed. 8vo, xiv.—247. Macmillan.

NOTICES TO CORRESPONDENTS.

Contributions should be *legibly* written, only on one side of the paper, and *must be* in the hands of the Printer eight days previous to their appearing.

When proofs are forwarded it is of the utmost importance that they should be corrected and returned without delay.

All Communications and Letters must be authenticated by the name of the writer, though not necessarily for publication.

DR. CHARLES KIDD, late of Sackville-street, London, has reverted to his attempts, by anonymously slandering, in his private capacity, the Proprietor of this Journal, to extort money, which, after the complete failure of his endeavour to recover it by law, he must be aware is due to him neither in honour nor justice. Suffice it to say that the Proprietor holds the following receipt, which he is ready to show to any gentleman who may desire to inspect it, or to produce publicly when called on, and which, as can be vouched by independent witnesses, was given by Dr. Kidd in full and entire payment of all demands, and to rid the Proprietary of any connection with him:—

Copy of Receipt.

RECEIVED of the Proprietor the sum of £3, for communications in 1866 to the MEDICAL PRESS.

CHARLES KIDD.

Sackville-street, Aug. 27.

Dr. Kidd has his proper channel for publicity through the law courts: he shall have none in our columns.

We are anxious to express our thanks for the many encouragements and suggestions we have received since our last. It is not practicable to print all the letters we receive, and some are evidently not intended for publication. The friendly hints so kindly offered will not be forgotten, the promises of support and expressions of goodwill will make us more zealous to deserve them.

Several friends mention the same points in almost identical words. Many express similar opinions in dissimilar terms. We shall only briefly refer to some of the points, and trust our friends will excuse our thus economizing space.

CUTTING THE EDGES.—This seems to have given general satisfaction.

HOSPITAL REPORTS.—We are thanked for giving full notices of the volumes of reports published by the hospitals, and asked to continue them. This we hope to do.

GLEANINGS.—This department seems to satisfy so many, that we must continue it.

REVIEWS.—We have always claimed the independence and honesty on which we are so much congratulated, and we have special arrangements to enable us to subject this department to the keenest scrutiny.

A Scotchman considers our Scotch edition rapidly progressing. We hope to surprise him by much more extensive improvements.

Three M.D.'s say the M. P. and C. is the only platform where complete independence reigns, and every fight may be fairly fought out, and where it is not the practice to burk either men or opinions.

Five friends declare that our "Articles may compare favourably not only with professional but general periodicals, are not characterized by cliquism, and certainly take broader views than those in any medical journal."

Lastly, we may thank those who promise to help all they can to extend our circulation, and once more state, that if all our friends were to do this, the profession would possess a journal equal to all its wants and worthy to represent it in the Three Kingdoms.

An old and valued Subscriber in Yorkshire is thanked for the following acceptable paragraph, which we extract from his letter of 31st ult:—

"I have always admired the just, liberal, and independent course of the PRESS AND CIRCULAR, and wish it every success."

The Medical Press & Circular.

ON AN ORGANIC CHANGE OF STRUCTURE OF THE HAIR, PRODUCED BY SYPHILIS.

By ERASMUS WILSON, F.R.S.

Diseases of the hair are, for the most part, nutritive; they consist in an excess or diminution of quantity; in a variation or loss of colour; in an alteration of toughness; and, less frequently, in a change of texture. The only disease heretofore reckoned as being due to an alteration of texture, is tinea or phytosis; but I propose to add another to the list—namely, one which results from an organic change in the structure of the hair proceeding from syphilis.

Constitutional debility, however induced, is apt to be followed by defluvium capillorum or trichorrhœa, frequently ending in alopecia. Trichorrhœa, consecutive to fevers and parturition, is sufficiently well-known to us; and loss of the hair is one of the usually recognised consequences of constitutional syphilis. Ordinary causes of debility generally act equally over the whole surface of the scalp; but the alopecia of syphilis commonly occurs in patches, as though following the corymbous type of distribution of the eruption on the general surface of the skin. Nevertheless, the final result is the same in both instances, the nutrition of the skin is disturbed, arrested for a while, and, the roots of the hairs, deprived of their nutritive juices, die, and then break away at their bulb, and fall out. These phenomena are the most frequently observed on the scalp, and less commonly in the whiskers and beard; and it is probable that the latter circumstance may be explained by the greater thickness of the stiff hairs, by the larger size of their bulb, and by the richer supply of blood-vessels distributed to their follicles. But these conditions, while they contribute to render the hairs more permanent, render them liable to morbid changes which have not hitherto been suspected.

A gentleman, aged 26, became the subject of syphilis for the first time in August, 1864. He describes the sore as having been slight, and healing without difficulty, with the aid of a saturnine lotion, and the internal use of iodide of potassium. Two months after this time he suffered with sore throat, of no great severity, and without any eruption on the skin. Four months later he found his hair coming off in considerable quantity, and at the end of another month, when he first consulted me, he was in a state of alopecia. At this time he exhibited symptoms of cachexia, his skin was pallid and cacotrophic, the sclerotics and conjunctivæ were pale, the tongue soft and indented, the mucous membrane of the fauces congested, and the tonsils swollen. He was a man of fair complexion and strumous habit, and the occipital and post auricular glands were enlarged from irritation, communicated by the unhealthy condition of his scalp. With the aid of alterative doses of the bichloride of mercury, in combination with the tincture of bark, and the local use of a mercurial pomade, the fall of the hair was arrested, but in consequence of his state of debility it was many months before new hair began to grow. It was at this latter period that he called my attention to the state of his whiskers and beard. The hairs had the appearance of being blackened every here and there, their normal colour being red, and upon being combed, or lightly pulled, the hairs broke off at these discoloured spots. I removed a portion of the diseased hair, and the appearances presented by it when examined with the microscope, are so remarkable, that I have thought them worthy of the attention of the profession, and now proceed to their description.

The hairs varied considerably in diameter, some were cylindrical, some flattened and twisted, some straight, others curled; and individual hairs often varied in breadth from 1-450th to 1-100th of an inch; the normal bulk ranging between 1-150th and 1-130th of an inch. Many of the hairs presented constrictions and enlargements, and at these points an organic change in the structure of the hair became manifest.

The diseased portions measured half a line to a line and a-half in length, and had the appearance of being composed of a dark cylinder enclosed in a transparent envelope, while closer examination showed that the fibrous structure of the hair was lost, and its place occupied by a dark grumous-looking substance. Moreover, the swollen or bulbous portion, was frequently split longitudinally through the centre, and exhibited an opening of considerable extent. The bulbous portion often measured 1-120th to 1-100th of an inch in diameter, while the size of the hair above and below the diseased point was 1-130th to 1-120th of an inch.

The essential peculiarity of structure of the diseased hair

was the arrest of development of the fibrous portion at its cellular stage; the dark cylinder, which forms the chief bulk of the diseased parts, being composed of large and small nucleated cells commingled with pigmentary matter, irregularly formed air-cells, and fragments of crystalline substance. The morbid structure may therefore be described as an expansion of the medulla, and, just as the medulla is the centre remainder of the hair unconverted into fibres, the morbid structure before us may be regarded as the unmetamorphosed cellular element of the hair retaining its primary cellular form. This cellular substance is continuous above and below with the medulla, and its homology of structure is very evident.

The envelope which surrounds the above described cellular structure, at first sight resembles the cuticle of the hair, and suggests the idea of an hypertrophy of the cuticle ; and the diseased hair appears to be composed of these two portions alone. But a more careful observation shows in some of the hairs a trace of fibrous structure in this situation, and leaves no doubt that the transparent envelope represents both the fibrous portion and the cuticle, the fibrous portion being sacrificed to the medullary element. Sometimes cells may be seen occupying the transparent envelope to its extreme boundary, and the surface of the cuticle is roughened here and there by a state of partial exfoliation.

The retention by the hair of its crude and early condition of a cell-structure in the morbid parts, serves to explain the brittleness of the hair, its tendency to break at these points, and the other curious process already mentioned of splitting longitudinally. I found one hair which had split up longitudinally for the greater part of its length, and the split portions were rolled up into short curls.

In conclusion, I venture to sum up the considerations suggested by the phenomena above described with the inference that the syphilitic cachexia which arrests the nutrition of the hair of the head and causes its fall, is apt, in the coarser hairs of the body, such as those of the beard, to arrest the development of the hair and cause the persistence of its early cell-structure ; moreover, that the same cachexia, which in the skin gives rise to pigmentary discolourations, also occasions deposits of pigment in the abnormal cell-structure of the hair.

REPORT ON OZONE.

By H. DAY, M.D.,

PHYSICIAN TO THE STAFFORD COUNTY INFIRMARY.

(Read at the General Session of the St. Andrews Medical Graduates' Association.)

(Continued from page 26.)

TESTS.

THERE is, up to the present time, only one recognised test for ozone—namely, the solution of iodide of potassium and starch. Owing to its power as an oxydizer, ozone acts readily on the potassium of the test compound, the potassium is thus separated from the iodine ; the iodine set free combines with the starch forming iodide of starch, giving a blue colour, which is the test. Test-papers, consequently, have been used, the papers being saturated with a solution of iodide of potassium and starch. Three forms of test-papers, thus prepared, are now in use, viz., Schönbein's, Moffat's, and Lowe's. Schönbein's papers contain ten parts of starch, and one of iodide of potassium ; Moffat's, two and a half parts of starch, and one of iodide of potassium ; and Lowe's, five parts of wheat starch and one of iodide of potassium. Lowe has also brought out another, in which, on the recommendation of the late Dr. Dundas Thompson, fifteen grains of chalk were added to each ounce of dried starch to prevent sourness ; this precaution produces great uniformity of effect. In a further research, Lowe has used what he calls "a dry powder test," using powders of wheat starch combined with iodide of potassium—one part of the iodide of potassium to five of starch being the most sensitive.

In order to detect the presence of ozone in the open air, the ozone test-papers, or the test powders, are ordinarily placed in a box, or ozone cage. The box is coloured dark within to avoid light, but air is freely admitted. This is the apparatus employed, I believe, by all the meteorologists who supply the reports to Mr. Glashier.

The amount of ozone is measured by the intensity of the colour, and is registered on Moffat's scale. There are objections to the ozone box, which objections have been well pointed out by Mr. John Smyth : this observer takes a dissimilar view to Lowe, who thinks that the velocity of air makes a distinct difference in the registration of ozone. He (Mr. Smyth) has devised an apparatus for securing greater uniformity of results ; it consists of a large aspirator, by which air is drawn with considerable velocity through a small tube so as to impinge at its opening into a tube of larger dimensions, against an extended surface of test-paper. By means of a cord connected with a clock, in which an extra weight is slung, a gasometer, which acts as the aspirator, is raised at an uniform velocity, and over which a pendulum gives complete control. A counterpoise is used to support the weight of the gasometer. Mr. Smyth shows, from a table of experiments, made with this improved ozonometer, that there is not much difference in the quantity of sensible ozone in two masses of air of equal volume, although they are moving at different velocities, in different directions, and under different hygrometrical conditions. He is further of opinion, that the ordinary test-papers do not register high enough.

Admitting, to a certain extent, the correctness of Mr. Smyth's arguments, there is a sort of fallacy in his experiment—viz., that he may be producing ozone in his apparatus, by drawing air with great velocity and much friction, through a small metallic tube.

The great objection to these tests is, that discolourations are produced by other agents than ozone, particularly by iodine, the chlorides, hydrochloric acid, nitrous and nitric acids. In the atmosphere, the last-mentioned acid, from its comparatively frequent occurrence, especially after electric storms, is a serious objection.

The late Dr. R. Dundas Thompson affirmed that even carbonic acid would affect these papers when they were very sensitive. As this latter point is of importance, I tested some highly sensitive paper with carbonic acid in its nascent form, and after it had been collected, and found that it occasioned evident change of colour.

It has occurred to my own mind that possibly a delicate test for ozone might be found, by observing the effect produced by the electric spark, when passed through rarefied ozonized air ; for this purpose, a globe, such as the one we have here, should first be filled with air that is saturated with ozone, and then be partially exhausted ; through this rarefied ozonized air, an electric spark should be passed, and the colour of the spark should be noticed and compared with the colour of the spark when passed through common rarefied air contained in the same apparatus.

But this experiment should be carried further by bringing the spectroscope into use.

As all gases are supposed to be the vapours of metals, it appears feasible that the spectrum would give a different band, or bands, with rarefied ozonized air, to those afforded by common air examined under similar circumstances and conditions.

I have not had, at present, the time or opportunity to carry out this experiment, and to report the result, but hope to be able to accomplish it before the meeting.

PHYSICAL PROPERTIES OF OZONE.

Whatever views may be entertained as to the chemical nature of ozone, it must be admitted to have certain physical properties which mark it distinctively. We have already seen, from the experiments of Soret, that it is heavier than oxygen. It is, also, quite insoluble in water; its power is intensely increased, so that air saturated with

it destroys dead organic matters with great rapidity. Thick india-rubber tubing is quickly eaten through by it, and ammoniacal products are speedily decomposed. In contact with ammonia, as Dr. Wood first pointed out, it forms white fumes like white fumes of chloride of ammonium, as though it combined with ammonium, as chlorine does, producing a specific compound, or salt, an ozonide of ammonium. We have proved, further, that it possesses a peculiar odour, thus, in relation to weight, diffusion, chemical action, and smell, it is, at all events, a distinct body, nor can, I think, its individuality be doubted by any, until these physical characteristics are explained away.

PHYSIOLOGICAL ACTION.

The physiological action of ozone has been studied by many observers, and with singular uniformity of results. It has been tested in regard to its effects on living animals, on dead tissues, on blood, on various secretions, and on various excretions, compound and simple. Let us first take under review the action of ozone on living animals.

If a warm blooded animal be placed in a glass chamber and be subjected to a stream of ozonized air, the oxygen of that air having been ozonized to the 12th part, and the influence of carbonic acid being entirely excluded, peculiar physiological phenomena are quickly displayed. The first sign is an irritability of the mucous surface of the nostrils, and of the conjunctivæ. There is often free secretion of saliva, and even profuse sweating in those animals that exhibit sweating; there is also thirst and dryness of the tongue and nostrils. These symptoms are succeeded by great rapidity of respiration, and soon by intense action of the heart. When the chest is auscultated in this stage, there is always dry-bronchial breathing, and a whistling sound as in the first or preliminary stage of acute bronchitis in the human subject. The effect of the ozone being sustained, cough manifests itself, followed by secretion of frothy fluid from the bronchial surface; this is equivalent to the congestive stage of bronchitis: finally, there is lividity of the skin of the nose, of the nostrils, and of the lips; great coldness of surface, gasping respiration, jactitation, and death, the death being often sudden. This may be said to resemble, most perfectly, the exudative stage of bronchitis. This order of symptoms or phenomena, as they, perhaps, had better be called, has been recognised by all experimentalists; it has been pointed out with particular care by our President, and my own experiments have been attended with corresponding results. There is, however, a remarkable difference in the periods of the phenomena observed in different animals, their order, nevertheless, being maintained in each case in which they are manifested. Guineapigs are peculiarly susceptible of the influence of ozone; these animals die in an atmosphere saturated with ozone, usually in about an hour, or an hour and a quarter, presenting, with much exactitude, the order of symptoms I have detailed above. Rabbits live longer than guineapigs, exhaling water from the lungs much more freely, and also micturating with greater freedom. Rats die with great rapidity. Mice display a greater tolerance. Pigeons resist the effects of ozone much longer than guineapigs, and may readily be taken out of the chamber in which they have been confined with guineapigs, apparently but little inconvenience at the period when the guineapigs are dead. If, when just removed, the chest is auscultated, the breathing, however, is found to be peculiarly sharp, dry, and cooing; the action of the heart being amazingly rapid, reaching even 240 beats in the minute, and the respirations from 90 to 100 in the same time. Pigeons, removed altogether from the ozone, when in this condition, will frequently exhibit the third stage of obstruction to respiration, and die. Frogs seem to have the power of resisting the action of ozone permanently, if they are allowed free access to water.

The animals on which I experimented were confined in this chamber.

MORBID PHENOMENA.

After death from ozone, the morbid appearances are principally confined to the respiratory passages. If an animal be killed during the first stage, the bronchial membrane is found to be dry, deeply congested at spots, the lung structure being ecchymosed, and both sides of the heart full of blood. In the second stage the whole lung is congested, the bronchial surface being red, the right side of the heart engorged, the left side empty. In the third stage the lungs are also intensely engorged, the bronchia surface paler, and filled with frothy fluid—the right side of the heart full—the left side empty. In cases where animals are removed from the chamber at the beginning of the second stage, and, after some exposure to the air, subsequently die, the morbid anatomy is rather that of pneumonia than bronchitis: in one experiment that I performed, the stage of hepatization was so distinctly marked that I could not have distinguished it, by the lung itself, from the hepatization of lung in the human subject after pneumonia.

It is worthy of remark that very young, or very feeble, or very old animals suffer much more readily from bronchitis, produced by breathing ozone, and succumb much more easily to its effects, than do full grown vigorous animals.

If animals die in the earlier stages of the disease produced, and especially if they die suddenly in such stages, the blood is found firmly coagulated in the heart, however quickly the body may be opened after death, but fibrinous separation appears never to have been discovered, the time for such separation to have taken place, having been evidently too short. Cadaveric rigidity is, also, in these cases, quickly developed; but, when the symptoms run on to the stage of lividity, the blood will remain fluid for several minutes after death, and the absence of rigidity of the muscles is proportionally prolonged.

THE ACTION OF OZONE ON ORGANIC COMPOUNDS.

Whilst the effects produced by ozone on numerous organic compounds has been found, by a large body of experimentalists, to be tolerably uniform, the explanations given as to the cause or causes in operation for producing such effects have been, in many instances, very different; but this is not more than would naturally be expected to be the case, when it is remembered that, up to the present time, so many theories have been promulgated and supported as to the true nature of this body.

Blood absorbs ozone with great rapidity, and oxygen is freely liberated. This capability of liberating oxygen has been said to reside principally in the red globules, from the circumstance that, when freed from fibrine and albumen, these bodies produce this identical effect. Further, when ozone is passed through freshly drawn blood, the red corpuscles lose their colour, and, in the process, are destroyed. M. Schönbein adduces, as an additional proof, the circumstance that such decolourised blood is no longer capable of producing the characteristic blue colour with the tincture of guaiacum.

Ozone passed through putrid blood destroys the putrescent odour, and restores coagulation. The long-continued action of ozone on albumen gives rise to the appearance of flocculi resembling fibrine, and Mr. Smee, Junr., believes these to be fibrine, but as they are not soluble in nitric acid, this point appears to be, to say the least, doubtful. M. Gorup-Besaner considers that the change undergone by albumen under the influence of ozone is, in many respects, similar to that caused by pepsine.

Upon urea ozone produces no greater oxidizing effect than any other oxidizing agent.

Ozone produces a rapid action on uric acid, causing it to be soluble in water, which water, upon being slowly evaporated, yields yellow prismatic crystals strongly resembling allantoin, and by a further evaporation of the water from which these crystals are obtained, a somewhat considerable quantity of urea may be procured.

On allantoin, alloxan, and creatin, ozone does not act at all, and upon leucin very slightly, if at all.

Ozone produces creatin from creatinin, and converts the solution from an alkaline into an acid one.

On casein, ozone produces a powerful effect, converting it, at one stage of the experiment, into a substance very like albumen, but a more continued action of the ozone occasions the formation of flocculi in every way resembling those produced by the action on albumen: when a stream of ozone has been passed for some time through milk it will, if kept for a few hours, lose its casein, whilst the fatty particle of the milk will remain in an unaltered state for a very lengthened period.

Neither fibrine nor bone-gelatin are at all acted upon by ozone.

If ozone be passed through bile, containing all its natural ingredients, it is very soon decolourised, but if it be freed from colouring matter, mucus and fat, no effect is produced on it.

Inosite and hippuric acid are not acted upon at all by it.

Whilst some chemists ascribe the various effects produced by ozone on organic compounds to an oxidizing process; others, on the contrary, attribute them all to the production of mere decomposition.

RELATION OF THE FACTS CONNECTED WITH THE OBSERVED MORBID PHENOMENA TO CERTAIN DISEASES IN MAN.

Amongst the several, indeed numerous, surmises as to the relationship of ozone to many diseases in the human subject, we have only one series of basic facts on which to ground any safe inference, these facts are, that the inhalation of ozone by inferior animals produces symptoms analogous, if not identical, to the symptoms of catarrh, bronchitis, and even pneumonia in the human subject, hence it might be inferred that the same agent, present in the atmosphere in excess, would light up those diseases. The great question then arises, whether there ever is such an excess of ozone in the air as would be likely to create such a result. If such were the case it would follow that man is more susceptible to the effects of ozone than the rest of the animal creation, otherwise, epidemics of these diseases, originating from the common cause, should infect the inferior part of the creation *at the same time* that it affects men, which connection of disease is certainly not yet proved, and to establish which there is no sufficient evidence. Again, there is no satisfactory proof that men are more susceptible to the effects of ozone than inferior animals; for in the laboratory, and during experiment, although irritation and pain in the head may be occasioned, and many symptoms like nasal catarrh occur; yet, for such an effect there must be with the man as with the animal, an excess of ozone quite appreciable to the ordinary senses.

When to the above facts we add the great difficulty of determining the actual existence of ozone in ordinary atmospheric air, we must hesitate to accept any sweeping conclusion in regard to ozone being a natural cause of disease. There is, moreover, this important fact to bear in mind, that taking animals of the same species and subjecting them to the same ozonic conditions, they suffer the same symptoms, although not in each case in the same degree perhaps. This rule should logically follow, although not necessarily to the same extent in regard to the human family, if it, in sections or masses, were subjected to the influence of the same universal agent, which is not the fact. To put forward an analogy:—if in the air under the influence of storm, or aught else, some subtle body, such as chloroform, could become equally diffused, in quantity sufficient to influence one individual by narcotism, it will not be disputed that all other individuals breathing the same air, would exhibit more or less the symptom, of narcotism. What, then, is the difference, if there be a difference? The difference must lie in what may be called individual power of tolerance of an active physical agent—a tolerance not even marked, in the same individual, at all times.

I put forward these objections not with the mere object of rebutting theory, but with a desire to enforce a more direct proof of theories plausible on their surface, but unquestionably open to serious objection.

Another view also presents itself to the mind, it is this—if ozone really causes disease, it is quite certain that the tests we have are altogether inefficient to record its presence when it *is* producing disease; or, there is some other agency at work which interferes with the physical facts without interfering with the determinate physical action.

I think it is possible that in studying ozone, admitting all the difficulties, and determined to trace out the rigid truth, we may, in time, discover a connection between the presence of ozone in the air and catarrhal and bronchial epidemics, but further than this I cannot concede the point, nor admit the smallest opening towards an argument tracing any other class of diseases to atmospheric ozone as their cause.

Finally, it has to be considered whether in regard to epidemics specially attributed to ozone—I mean catarrh's, bronchitis, and the like—there are not other perfectly efficient causes at work to excite these maladies independently of ozone.

The recent report of the Registrar-General shows so definitely the influence produced by simple variations of temperature in this respect, that, really, in ignoring these variations, to look for more obscure causes, seems like going from the real and ascertained to the problematical, without any other reason than love of novelty.

CONCLUSION.

1. The history of ozone through all the steps that have led to its discovery, is singularly interesting and beautiful. The discovery, throughout, has been conducted purely on the constructive or synthetic method, and, in all its early stages, has been the result of simple observation apart from theory. Progress, in regard to it, has thus been made by long but even steps, each independent observation being confirmatory of what has passed before, and tending, ultimately, to the same end.

2. There can be no escaping, at this moment, from the theory that ozone is a modified condition of oxygen, indeed, is oxygen plus force, which force is probably used in condensation—in other words, the power or capability of oxygen to combine with itself.

3. The artificial production of ozone, and the quantity that can be produced; or, rather, the quantity of oxygen that can be transformed into ozone is most clearly and distinctly defined; in fact, in the laboratory, the production is an absolute verity as pure as the production of oxygen or chlorine. For the production of ozone in the laboratory, no method is so good as that accomplished by the aid of the induction coil. The production of ozone in the air, if it be there, is not yet in any way definitely understood.

4. The ordinary tests for ozone are imperfect, not because they will not prove the presence of ozone, but because they prove too much—that is to say, the presence of other bodies also common to the atmosphere.

5. In its action on the body the effects of ozone seem to be confined to the respiratory passages and structures, in fact, it is purely local in its action, resembling closely diluted chlorine and diluted bromine in vapour, the phenomena induced, varying in intensity, may be catarrhal, bronchial, or pneumonic, nor is there any evidence of any other class of diseases from ozone.

6. Ozone administered so as to produce death, promotes conditions clearly indicative, as I have already stated, of local action confined to the pulmonary system. The conditions are those of oppressed secretion, vascular congestion and exudation.

7. The relation of ozone to disease, if there be such a relationship, is confined to disease local in its character, and to one part of the system—the respiratory. Beyond this there is no logical argument whatever, and even this must be accepted as problematical until other potent influences are estimated as causes on the principle of exclusion.

8. On dead matter, ozone exerts a powerfully-destructive action, resembling in this way chlorine, iodine, and especially bromine.

9. Ozone is a disinfectant and deodoriser belonging to those bodies which disinfect and deodorise by resolving and decomposing into primitive and innocuous forms, competing in this respect with substances already named—*i.e.*, chlorine, bromine, and iodine. It possesses these qualities in a less degree than chlorine and bromine, and is, in many cases, not so applicable as iodine.

10. As a preventive of disease, ozone can only act by destroying organic animal poisons, in which respect it may be compared with the substances I have more than once named. With regard to the disinfecting and deodorising powers of ozone, I would refer you to the opinions of the late Dr. Barker, contained in the Hasting prize essay for 1865. The subject of comparison, and indeed the whole subject of deodorising and disinfecting, is there so admirably, so exhaustively discussed, as to leave, it seems to me, nothing further to be said on the subject.

11. Lastly, as a remedy. In the form of ozonised oil, of ozonised ether, and ozonised water, it once more ranks with a similar combination of remedies, containing chlorine, bromine, and especially iodine. Whether, in any respect, it may prove to have greater advantages than the last named trusty and ready agent, can only be conclusively arrived at by determining whether it will do what iodine will *not* do, and this can only be decisively made out by applying to it the test of inductive philosophy—a rigid exclusion of all that is ineffective.

And now, Mr. President, I must bring this imperfect report to an end, and, in doing so, I think it will be impossible for me to do better than by taking, for its final part, a few lines from the preface of a much more ambitious, and far more deserving work. The lines are these:—

"If this publication be only the more solemn funeral of my remains, I wish it may be known that I die in charity and in my senses, without any murmurs against the justice of this age, or any mad appeals to posterity. I declare I shall think the world in the right, and quietly submit to every truth which time shall discover to the prejudice of these writings, not so much as wishing so irrational a thing as that anybody should be deceived merely from my credit."

THE GERMS OF CHOLERA AND THE MEANS OF THEIR DESTRUCTION.

By ARTHUR ERNEST SANSOM, M.D., M.R.C.P.,

PHYSICIAN TO THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY-ROAD.

In my last communication on the cholera poison, it was shown that both analogy and direct observation tend to establish the correctness of the theory which alleges that this poison is an organized material of animal or vegetable origin. The object of this paper is to enquire whether the poison obeys the same laws which govern other germs possessing life, especially whether those influences which destroy the latter destroy also the former. If we can come to a definite conclusion, that conclusion must have a two-fold value, for it will not only establish the truth of the theory, but it will be a most important guide to practice.

In this enquiry we have to consider the agents which destroy the vitality of the lowest forms of organized (animal or vegetable) life; to investigate the mode in which they accomplish such destruction; to determine whether such agents can be employed within the living body, as well as externally to it, and to apply the practical test of experience whether a therapeutic treatment founded on deductions from the foregoing observations can be, and has been successful.

If it be granted, as, indeed, the science of the present day compels, that certain diseases originate from organized germs, how may these germs be destroyed? When such germs affect the exterior of the body, it is obvious that they may be removed by physical, as well as destroyed by chemical means. Thus, pediculi and their ova are removed from the skin or the hair, or vegetable growths are taken away with the hair-roots by epilation, or the foul crust of an ulcer is lifted from its surface. By indirectly physical means, also, organized bodies are expelled the alimentary canal, as parasites and their ova, by the action of purgatives. Methods of destroying organized particles on the surface of the body have been used since the earliest days of medicine, though the *rationale* of the process has not been well understood. What was the operation of the actual cautery but the oxidation of irritating animal compounds? What was its use when applied to wounds produced by the bites of rabid animals, or by the virus of snakes, &c., but a method of employing an oxidizing disinfectant? It is needless to state that chemical caustics also have been employed from the earliest times. It was known that they destroyed a virus which might otherwise be absorbed into the system, or that they made the surface of a wound more healthy in appearance, but the reason why was almost unknown. It is now understood that the metallic salts which we use as caustics unite chemically with the organic and organized materials with which they come in contact; that they alter the chemical constitution of the one, and disorganize (by a chemical change) the other. Pasteur showed that the air is full of septic germs. On the surface of an ulcer these germs find a soil suitable for their growth and propagation. According to Lemaire pus itself is a product of the growth of organized particles in pus or mucus. A metallic salt like nitrate of silver unites chemically with these matters with which it comes in contact. It thus not only arrests the vitality of these living particles, but it changes the albuminous material in which they exist, and renders it a soil unsuitable for their growth. For the attainment of a similar end, other substances besides metallic salts have been used. Lotions of sulphurous acid or of permanganate of potash have been employed in cases of external parasite formations. The avowed object of these applications has been the killing of the organized structures, causing the ostensible phenomena of the disease. Lastly, in addition to many other means of the same kind, carbolic acid has been used by Lemaire, Déclat, Crookes, Lister, Simpson, and others, with distinguished success. To continue the method of argument which I adopted in the former communication, I will enunciate the following as—

Proposition A.—That the germs of zymotic diseases are destroyed by disinfectants and antiseptics.

Processes of fumigation for the disinfection of dwellings, are known to be of the remotest antiquity. They formed part of the duty of the priests under the Levitical law. Burning sulphur, according to Ovid, was used by Roman shepherds to purify their herds and flocks. Wherever the contagiousness of disease was recognized, some measures for purification and disinfection were usually popularly adopted. Until quite lately, chloride of lime was almost universally employed in localities affected with transmissible disease. The object of all such processes was the destruction of the *materies morbi*. The mode in which they accomplished this destruction has been, until lately, imperfectly understood. Agents for the destruction of infectious disease, producing particles, may be arranged under three divisions: —1. Those agents which alter the chemical constitution of the *materies morbi*. 2. Those which have a double action, altering the chemical constitution, and specifically arresting the vitality of infecting particles. 3. Those agents which, though exerting no chemical influence, yet have the power of killing the germs.

I.—Of the first class, essentially chemical disinfectants, the usual mode of action is oxidation. They exert more power of deodorization than the other classes, because they change the nature of the gaseous products of putrefaction. Of this class the most powerful and practicable agent is chlorine. Chlorine, in the presence of organic matter, combines with hydrogen, liberating oxygen.

The metallic salts come under this class, the most useful oxidizing agent among them being permanganate of potash or soda (Condy's fluid.)

II.—The second class of disinfectants comprises those

which affect morbid germs both chemically and vitally. Sulphurous acid is a type of this class. It alters the chemical constitution of organic bodies by deoxidizing them, but it has an action over and above its chemical action in destroying the life of organic particles. If its power of checking organic change depended only on its deoxidizing or other chemical properties, its value would be limited on account of the large quantity which would be necessary to effect the necessary chemical decomposition; but it is not so, for it has, besides, a special power. "No agent," says Professor Graham, "checks so effectually the first development of animal and vegetable life." The occurrence of fermentation, according to Professor Miller,[1] is prevented "by solutions containing *traces* of sulphurous acid or the sulphites." Mr. Crookes states, in his admirable report to the Cattle Plague Commissioners, "Sulphurous acid acts in many cases through its affinity for oxygen, but it possesses also great antiseptic powers of its own, so that a slight exposure to it is sufficient to destroy the vitality of germs." It is evident, therefore, that sulphurous acid and the sulphites have a twofold action on organic and organized matter.

III.—Bodies of this class act alone on the organized material; they induce no chemical change, but they *kill* the lowest forms of animal and vegetable life. Such a body is carbolic acid. Though this substance is of comparatively recent introduction, compounds containing it have been used from time immemorial. Pitch, tar, and gum resins were used as fumigations in the early ages. Mr. Crookes' carefully-contrived experiments on carbolic acid have shown that it exerts upon organic matter no chemical influence whatever, and neither promotes nor retards any purely chemical change; "but it has a special action on the fermentation induced by organized matter; it not only arrests it instantly when in progress, but it prevents the development of future fermentation." The mode in which it accomplishes this is by attacking vitality. "It may be considered as definitely proved that the vapour of carbolic acid in the atmosphere exerts a special selective power on all minute organisms possessing life."[2] Although its action is catalytic and not chemical, carbolic acid appears, from the results of recent research, to be the most energetic of all disinfectants. Lemaire showed that very small proportions of carbolic acid were sufficient to destroy the effects of myriads of organized particles. Crookes showed that a solution containing one per cent. of carbolic acid at once arrested the vitality of yeast, and though the yeast was afterwards washed with water, it could not be made to re-excite fermentation. It has been used as a disinfectant in nearly all zymotic diseases, including the cattle plague, as well as in cases of pus formation and unhealthy inflammation of almost every class occurring on the surface of the body. For further information on this point I must refer to Lemaire's book[3], and to the recent writings of Lister[4] and Sir J. Simpson[5].

Whatever be the disinfectant chosen, I think that it is scarcely possible that a doubt can arise as to the efficacy of the practice of disinfection. Overwhelming evidence has shown zymotic disease to be the result of the operation of organized poisons, and the practical experience of thousands has indicated that the spread of disease can be checked by measures of disinfection. We come now to

Proposition B.—That the germs of cholera are destroyed by disinfectants and antiseptics.

If we have shown with great probability already that cholera is the result of the actions of an organized germ upon the body—if we agree that the action of antiseptics &c., is to destroy organized germs, and if we find that antiseptics, &c., have checked the progress of cholera, it is surely fair to infer that antiseptics, &c., act in such a case *by* the destruction of germs. Conversely, if we agree upon the usefulness of antiseptic measures, we are constrained to admit that cholera has for its cause an organized poison. Of the efficacy of disinfecting measures in arresting the spread of cholera, I consider that the history of late epidemics has given us many proofs. The Health Report of the Medical Officer of the Privy Council (which will become a classic on the subject of cholera), contains a vast amount of evidence tending to show the value of systematic measures of disinfection during an outbreak of cholera.

"Too much importance," says Mr. Simon, "cannot be attached to the duty of thoroughly disinfecting without delay, with chloride of lime or otherwise, all discharges from the stomach and bowels of persons under the epidemic influence, as well as all bedding, clothing, towels, and the like, which such discharges may have imbued."[1] Mr. Simon gives an admirable general memorandum on disinfection, recommending, as the agents which most commonly prove useful, quicklime, chloride of lime, carbolic acid, sulphate of iron, perchloride of iron, and chloride of manganese. In Dr. Buchanan's report of the outbreak in Southampton, it is stated that, on an average, twenty gallons of carbolic acid, and 30lbs. of chloride of lime were used daily for the purposes of disinfection. Similar disinfecting measures were adopted in every metropolitan district. It is clear, therefore, that the value of the process of disinfection must have forced itself upon the minds of a large number of those whose duty it is to guard the public health; and it is certain that a very large amount of public money was spent in disinfectants, and the mechanism of their employment. Now the very application of the process of disinfection necessarily presupposes that cholera is a zymotic disease—a disease propagated by organized particles, which it is the function of disinfectants to arrest or destroy. We are, therefore, in this dilemma—either we must agree that cholera is caused by a transmissible organic poison, or there has been a most fearful waste of public money, as well as an unfortunate misapplication of the brains of learned men. There can be little doubt, I think, as to which conclusion we shall come to. Having investigated the operation of disinfecting agents outside the body, we arrive now at

Proposition C.—That the germs of zymotic diseases are capable of destruction within the living body.

If we look over the list of those substances which have powers of disinfection, we see many which have been used in zymotic disease without an idea being entertained as to their possible influence upon the germs of disease—such are chlorate of potash, and the chlorine compounds which have been used in diphtheria, or perchloride of iron in scarlatina, and mercury compounds in the various instances of morbid infection. The very astringents also which have been used in diarrhœa, *à fortiori*, tannic and gallic acids, act as powerful deoxidizing agents.

In the majority of zymotic diseases the morbid poison must exist in the blood; therefore it is necessary that the agent which shall destroy the poison shall also be capable of absorption into the blood. Of the agents which I have mentioned as capable of destroying organized particles *outside* the living body a very large proportion is capable of absorption into the blood. The question then occurs—Which is the most practicable agent to employ, as easily absorbed, as efficacious in its action on the poison, and as leaving uninjured the circulating blood? The answer which I have formerly given to this question has been, the sulphites.

But here comes the objection of the writer of "Cholera Theories"—"Here we beg to remind him (myself), that had he followed the most recent investigations on this subject, he would probably have accepted the conclusion that the sulphites would destroy the vitality of a patient's blood more readily than germs such as those, to the presence of which he ascribes the phenomena of cholera."[2] Now the most recent record of investigations which I have seen, a paper by Dr. John Polli, of Milan, in the *British*

2 Medical Press and Circular, September 4, 1867, p. 228.

Medical Journal, for November 16th, 1867, proves the exact converse of the startling statement of my critic. Indeed, I am perfectly at a loss to conjecture what investigations ever undertaken prove, or seem to prove, his hypothesis. It is possible that he may have derived his opinion from a statement, not an investigation, by Prof. Claude Bernard, who says—"We cannot neutralize these ferments in the living organism, it is impossible, because to effect such a purpose, it would be necessary to interfere with the character of the blood to such an extent, that it would be no longer capable of maintaining life." Here it is to be observed, first, that Bernard, unlike the reviewer in Cholera Theories, embraces the zymotic theory *in toto*. He readily admits the existence in the blood of morbid germs, but denies our power of killing them without our also deteriorating the blood. And what is his reason? No doubt he thought when he penned the foregoing sentence that a neutralizing agent would act by chemical means. Now, I readily admit that if sulphurous acid or the sulphites acted merely as deoxidizing agents, to neutralize the ferment it would be necessary gravely to interfere with the character of the blood. But I have said that these agents do not solely or chiefly act by virtue of their chemical power. They act by arresting the vitality of the lowest forms of organized particles, such as zymotic poisons have, in my former paper, been proved to be.

The *à priori* objection is, therefore, disposed of. It is no more impossible to destroy the germs of disease without impairing the vital properties of the blood, than it is to destroy an entozoon without impairing the organic structures of the higher organism which contains it.

(To be continued).

Lecture.

CLINICAL LECTURE,

DELIVERED IN THE

NORTH CHARITABLE INFIRMARY AND CITY OF CORK GENERAL HOSPITAL.

By Mr. SHINKWIN,

JUNIOR SURGEON TO THE HOSPITAL AND DEMONSTRATOR OF ANATOMY QUEEN'S COLLEGE, CORK.

GENTLEMEN,—Prostatic disease is, as you are aware, peculiar to old age, and the patient who suffered from it in my ward was, in the most remarkable manner, the very picture of the class that Brodie so faithfully and truthfully describes, in his lectures on "Enlargement of the Prostate Gland." His hair was grey and scanty, the white zone was beginning to show itself around the cornea, the body was wasted, the skin dry and parched, the countenance expressive of that peculiar anxious look so characteristic of suffering from urinary disturbance, and when he walked across the ward, you might see that he did so with the body bent slightly forwards, and that the hands supported the genitals, in fact, the whole man showed but too plainly that the frame which had once been strong and vigorous, had now nearly approached that period of life, when he should soon shuffle off the scene and leave others to fill the place he was at present occupying.

On referring to the notes of his case, I find that Murphy was aged 60, and that he had been suffering from retention of urine, fully a week before admission. On inquiring more fully into his case, we find he has never had an attack of gonorrhœa, and that this is the second time he has had stoppage of water, the last being about 8 months ago. At that time a catheter was used three or four times, and after that he was able to pass water by himself, but in a much smaller stream than before.

Dr. O'Sullivan saw him on admission, and found the bladder greatly distended; after some little difficulty he passed a No. 8, gum elastic catheter, and drew off a large quantity of water. The next morning you saw me perform the same operation, and relieve the man's bladder of a good supply of urine, and you might have perceived that I did not require to use any pressure to induce the water to pass through the instrument, thereby showing that the muscular fibres of the bladder were not the cause of the retention, but that some mechanical obstruction stopped the urethral passage.

The report, after being seven days in hospital, is:—Catheter used morning and evening; patient unable to relieve himself. Just at this time I happened to be in consultation with one of our most eminent surgeons, on a case exactly similar to Murphy's, and I thought it my duty to give him the benefit of the advice. This surgeon strongly advocated the use of opiate enemata or suppositories, and, as you may remember, we tried the enemas in this man's case; well, what did they effect? I directed the nurse to give him a tinct. opii. and starch enema, a drachm to two ounces, and the report after its administration is, "no improvement in passing water; urine highly acid." He was also ordered a warm bath, and as the urine was highly acid, he got a mixture of liquor potassæ, bicarbonate of potassæ, and bicarbonate of soda, and to have the enema repeated.

After the administration of the second enema, he had no pain, even with the bladder fully distended, but, with all that, the expulsive power remained the same as before, so, of course, we had to use the catheter; but this much I must say, it entered the bladder more freely than before we used the opiate enemas. On the 12th November, 13 days in hospital, the report is—"Has not required the catheter for the past three days." I should here mention that for the last five days he has been taking bromide of potassium in five grain doses three times a-day. But the result shows how cautious we ought to be in letting our hopes deceive us, as to any permanent benefit accruing to our patient, from any of the plans of treatment we have just now enumerated, for the day after the report is—"About twelve o'clock yesterday, Murphy complained of intense pain in the perineum, and a burning desire to pass water." The catheter was passed easily first, then with some little difficulty, then at the third time with greater difficulty, and on the water flowing at this introduction, it was highly tinged with blood.

On seeing this state of affairs, I did not wish to use the silver instrument, but tried the gum elastic of the same number. It passed easily until it arrived at prostatic portion of urethra; when there it stopped, and no inducement of mine could possibly get it further, but on it should go (as the man's bladder was full of urine), either through the prostate or in the course of the urethra; preferring to guide it, if possible, through the latter, I passed the index finger of left hand into rectum, and found lying on it an enormously enlarged prostate. With some little difficulty the point of the catheter was slipped over it, and the instrument glided safely into the bladder, and the water was permitted to flow off.

On my withdrawing the catheter, what a picture of pain and suffering poor Murphy presented. He was actually bent double, not, as he said, with acute pain, but with the most awful burning sensation in the perineum. It was so intense that he could neither content himself in or out of bed. And now, for the first time, I noticed that the drops of urine in the catheter were tinged with blood.

This was, indeed, a sad state of affairs. Some of the symptoms may have been accounted for by the idea that, there was an abscess of the prostate gland, but from the notes of the case up to this period, there was nothing to warrant us thinking so. I do not think myself there was, though others who saw the case appeared to imagine that, there was a collection of matter in the gland. The probability is, that when the instrument was being used a second time and not found to go in easily, that a little more force than requisite was applied, and that in this way some of the mucous lining of the canal was ruptured, which, of course, laid bare the parts to the action of the urine. This, I think, I

am borne out in supposing, as there was no pain whilst the catheter was being introduced, or whilst the urine was flowing through it; but on the withdrawal of the instrument, when the protecting power of the catheter was gone, and when the last drops of the water came into contact with the passage, it was only then, and not until then, that the patient complained of the irritation. I thought, if he allowed the catheter to remain in the bladder, it would be of some service to him, but he would not consent to do so.

He was immediately ordered a very warm hip-bath, and a mixture of tinct. opium and liquor potassæ. On the 16th, that is his seventeenth day in hospital, the report is, "after drawing off the water to-day, it was noticed, for the first time, to be quite cloudy—and, on being tested for pus with liquor potass., a large quantity seemed to be present. He now has no pain in urethra, and says he thinks he is getting well." We stopped all medicine, and the last report of his case is dated the 20th, twenty-one days in Hospital:—"Passes water perfectly, very little pain; he left hospital of his own accord, as he wished to be at work.

Had we an hospital full of prostatic disease, I could not have shown you a more perfect case than that of Murphy's. He was a type of this class of case, and the reason that I direct your attention to it so closely is, that when you are hospital-surgeons yourselves, such cases will frequently come under your notice; indeed, not only in hospital but in private practice, such cases are constantly under treatment.

Let us ask ourselves the question, what hindered that man from passing water when his bladder was full to overflowing? It was not want of power in the bladder, for, the moment the instrument was introduced, you saw how freely the urine flowed off without any pressure whatsoever on the abdomen. It was not stricture (so called), for you saw me, and you heard that Dr. O'Sullivan passed a No. 8 instrument without the slightest difficulty. What then hindered the patient passing water, when he willed it, and when the muscular fibres of the bladder were sufficiently strong to eject the urine through the silver or gum-elastic tube? Obstruction to the water there was—but where? The obstruction was evidently in that portion of the urethra surrounded by the prostate gland. If you read up the authorities on this subject, you will be told, the third or middle lobe of the prostate, when enlarged, is the chief cause of inability to pass water; such is certainly, in a great measure, the case; but, I think, the lateral lobes, when increased, in size, have just as much to do with the retention as the middle one, and far more frequently prevent us from passing a catheter than might be at first imagined; the middle lobe merely elongating that portion of the canal that it surrounds, and slightly flattening it, whilst the lateral lobes by becoming of unequal size, push the canal out of its natural course, and, in this way, produce obstruction to the entrance of the instrument. If the middle lobe were the only one enlarged, there would, in my mind, be little or no difficulty in passing an instrument, as the obstacle would be pushed out of the way as the instrument passed on. This would occur even where, as I have seen it as large as a small orange; but when we find, as in the case before us, that the catheter passes up to a certain point, and then sticks there, rest assured one of two conditions are present—the mucous membrane of the urethra has become very much inflamed, or, one of the lateral lobes has become so enlarged as to push the canal more to one side than the other. When such a state of things does occur pass your finger into the rectum; by doing so, you straighten the passage, you tilt the point of the catheter in the proper direction, and you save your patient. Woe betide you, if in such a case you use any undue force; many a poor unfortunate has to curse the day he permitted an unskilled hand to use a "Prostatic Catheter," the most delicate manipulation, the most exquisite sensitiveness, between the operated on and the operator, is required in such cases; in fact, an almost magnetic influence, to know when to stop, and when to persevere with anything like pressure on the parts. Believe me, gentlemen, such is not learned in a day. It is only by long and careful practice that such knowledge can be acquired. One man has passed an instrument where others have failed, but oftentimes the post-mortem room has revealed destruction to the most sensitive portion of the human frame, and that by using undue violence. Let me impress upon you this maxim, never use force in passing either a bougie or catheter, sooner make your patient submit to an operation, than that he should linger out a few weeks with a false passage.

Never try to deceive a patient with prostatic disease. Tell him honestly and candidly, that you will be able, in a great measure, to alleviate his sufferings, but you might as well hold out hopes to him of making his grey locks black, or restoring to him the keen eyesight of his youth, as of curing him of enlarged prostate. The gland is a purely mechanical obstruction, it is the flood-gate at the mouth of the canal, it must be opened to let the waters pass—it is not stricture—that is, it is not muscular contraction. It is the pressure of a body under and around the canal, which body must be pushed aside, and the only way you can accomplish this, is by using a full-sized catheter, either gum-elastic or silver; I generally use one such as this in my hand. You may perceive it is longer than the ordinary ones, and more curved; if it were not so, it would come in direct contact with the obstacle we want to push out of the way.

You may here ask me, and very fairly, why not use a gum-elastic instrument? My experience tells me (though I know it differs from some high authorities), that a silver instrument, such as this, can be used far easier than an elastic one. I have found it in some cases utterly impossible to introduce an elastic, but this curve of instrument, named by a gentleman I used to attend "The Infallible," never failed me in the hour of need. I grant you the gum-elastic has the advantage over the silver when required to be retained in the bladder, but I doubt very much whether such practice is advisable, at least for any length of time. Surely the coats of the bladder are irritated enough by the pressure of the tumour, and this irritation should not be increased even by the use of the flexible catheter, used by Thompson, more especially in a patient where there is only chronic, not acute enlargement of the gland. If the patient can pass no water for weeks together, then, indeed, Sir Henry's flexible tube will be a blessing to the sufferer, and a boon to the surgeon; but the generality of these cases occur in old gentlemen who, after sitting at a dinner party, leave a hot room, full of wine and punch—the gland becomes engorged, and retention is the result; or a far more frequent cause is, if the old gentleman has been spending his evening, after the dinner party, in some fascinating female society (for these old chaps are generally bachelors,) and when he goes home, he begins thinking of sweet smiles and the silvery voices of his late companions, this, and other causes, result in an engorgement of the part, and retention of urine follows. What is to be done? Relieve your patient as quickly as possible; if he consents to it, leave the catheter in the urethra for two or three hours, not longer, but surely in such a case you would not condemn your patient to wear a long tube, day after day, dangling from his penis. I for one would much prefer using the catheter daily for him, until all spasm had subsided, and, by doing so, you may rest satisfied that all would be done for your patient that could be done; that you had exercised in his favour all your skill, and that you have, to the best of your abilities, tried to make his sufferings as endurable as is possible within the art of surgery.

PRIZES FOR 1869 OFFERED BY THE ACADEMY OF MEDICINE OF PARIS.—1. On the Diseases of the Cerebellum, £40. 2. On Sclerosis in the Different Organs, £24. 3. Clinical History of Insanity with Fancied High Rank, especially in a Therapeutical point of view, £40. 4. On the Return of the Uterus to the ordinary state after confinement, with medico-legal deductions as to the time since which a woman has been delivered.

Hospital Reports.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

Dr. FLEMING'S Surgical Clinique.

IV.—HERNIA AND HYDROCELE—DISTRIBUTION OF TRUSSES.

Dr. Fleming brought under notice of his class the several cases of application for trusses at the last monthly distribution. (January 6th.) The number was 26.

Two occurred in females from femoral hernia; two in children, one aged two years, and the second four months; the remaining number in males, their ages varying from 35 to 75, and the variety of hernia being inguinal and inguino-scrotal. There was no case of femoral. Dr. Fleming outlined the several varieties of forms of the sacs of hernia, and illustrated the most usual by reference to the cases then under observation — the cylindrical, the globular, the conical, the pyriform, and the pouched or sacculated were specially observed. He considered those as points of practical import, and especially so in establishing differential diagnosis. As before remarked, the femoral were of the globular form. In the cases presented at this sitting they were so, and were small, and did not encroach over Poupart's ligament. He remarked on the comparatively small size of that variety of hernia both in male and in female. There were yet exceptions, however, as several plates illustrated, and one remarkably so, in a female, unmarried, in whom the hernia reached even beyond the middle of the thigh. He could not bring to his recollection ever having met with femoral hernia in the young male child. He did once or twice in the young female child, but at that age, and in that sex, it was extremely rare to meet with even any form of hernia. The case of scrotal hernia in the boy, aged two years, presented peculiarities worth their attention, as in all other cases of enterocele, namely, its peculiar clear sound on percussion; but, in addition, Dr. Fleming showed satisfactorily that it was translucent, a condition intelligible from the remarkable thinness of the scrotum and of the hernial sac, containing within it a loop of a thin intestine, distended with flatus, and equally thin-walled. Such condition of translucency was by no means uncommon in the large scrotal "enterocele" of the young child.

The number of scrotal herniæ witnessed in the men was remarkably large, and many were double. In one instance, the hernia reached the size of a cocoa nut on each side, and no application had ever been made previously for a truss, although they had existed for four or five years. It was surprising how careless people appeared to be respecting the presence of herniæ and of hydroceles. Their painless and gradually and almost invariably progressing growth may, perhaps, in some measure, account for such remissness—a remissness by no means confined to the lower ranks of life. He had often detected hydroceles and herniæ, single, double, and co-existent, of very large size, in which the attention of the surgeon was never directed to their presence by the patient, although many of his ailments complained of had special connection with them. In dyspeptic cases especially, he recommended the examination of the abdomen, particularly in the ordinary seats of hernia. Often and often the discovery of a hernia and the subsequent application of a well-fitting truss relieved such symptoms, which under previous treatment were totally unmanageable. Such class of case immediately now, accidentally presented itself, and he begged their special attention to it. A man with a fully-reducible scrotal hernia complained of considerable suffering from flatulence after meals, and said that his stomach "bulged out," as he termed it, during the paroxysm of such attack. Dr. Fleming had the abdomen fairly exposed, and a "ventral" hernia at once caught his attention.

The more important diagnostic features of such hernia were detailed and contrasted with those of umbilical hernia. Remarks respecting the co-existence of hydroceles and hernia were already disposed of, and did not now require repetition. He tapped two such vaginal hydroceles, in one of which the testicle was considerably enlarged, and lay below the fluid, the hernia being distinct above it.

There were three cases of "direct" inguinal hernia very well outlined. Dr. Fleming remarked the resemblance in form of the sacs of such hernia to those of femoral hernia, and pointed out their diagnostic characters. The facility of tracing with the fingers along the under border of Poupart's ligament in such cases, without any interruption, to the insertion of that ligament into the spine of the pubis, was an admirable assistant to the decision of the surgeon. The test by percussion, as forming an important item in establishing the differential diagnosis between hydrocele and scrotal enterocele was illustrated in the several cases as they presented, and the paramount value to the surgical student of the study of those monthly exhibitions of cases for truss-issue was strongly enforced. From rough notes taken by Dr. Fleming during the last fifteen or sixteen years, he found that the average annual number of applicants for trusses was seldom under 400—often above it—and he need not add the immeasurable instruction derivable from the examination of such cases, both to surgeon and to student. He would take the earliest opportunity of making some remarks on "hydrocele of the hernial sac."

MILITARY HOSPITALS.

A few weeks ago we gave the particulars of two interesting cases from the Army Blue Book. At the request of numerous friends to whom that heavy volume is inaccessible, we shall continue to avail ourselves of the mass of material it contains, and proceed at once to relate two cases of heart disease treated by Staff Assistant-Surgeon, J. F. Foster, who adds to each a few remarks:—

Case 1.—*Mitral Disease of the Heart, with Enlargement of the Fibrous Rings and intervening Fibro-Cartilaginous Mass, associated with Hypertrophy and Fatty Degeneration of the Organ.*

Private J. M'C., aged 31, a soldier of 11 years' service, seven and a half of which have been passed in India, is admitted into the regimental hospital of the 91st Highlanders, at Dum Dum, on the 27th April, 1866, complaining of vertigo and shortness of breath, with cough and hæmoptysis. These symptoms have only been present for the last two days; but for six months past he has been losing flesh and subject to palpitation after any unusual exertion. He has not, however, applied at the hospital for relief until this date.

On physical examination of the chest, consolidation of the apices of the lungs is evidenced by increased vocal resonance, bronchial respiration, and dullness on percussion. His breathing is very short and quick, and scarcely any expansion of the chest takes place during inspiration. Heart sounds feeble and distant, and very slow, only 40 contractions occurring per minute; no abnormal murmur detected. He is much emaciated, his appetite bad, and he suffers from profuse night sweats; he has also a troublesome cough, with mucous expectoration slightly tinged with blood.

Treatment.—Quiniæ et ferri citratis, 5 gr.; aquæ, 1 oz., *ter die*; olei morrhuæ, ½ oz., *ter die*. Port wine four ounces daily.

April 29.—There is much more blood in his sputa today. Pulse 36, feeble but regular; tongue furred.

April 30.—There is very little hæmoptysis this morning; but his breathing is much oppressed, so that he requires to be propped up in bed. Pulse 32. In the evening he is in just the same state; pulse 32 only and quite regular. He says he feels better, but occasionally giddy. There is no anxiety upon his countenance, and his breathing, though short and quick, is not laboured.

At 11 o'clock P.M., without any previous complaint, he

suddenly gave a scream and, before assistance could reach him, expired.

Sectio cadaveris eight hours after death.

External condition of body much emaciated.

THORAX.

Heart.—Some ounces of fluid in the pericardium. Heart large and overlaid with fat. The ventricular walls much hypertrophied, but paler than usual; that of the left ventricle being one inch thick. Large clots filled both ventricles, and the aorta was plugged throughout its whole extent. Mitral valves rigid, and studded with small fibrous deposits; the columnæ papillares degenerated into a firm pale substance, with very little muscular tissue remaining. The fibrous rings and intervening fibro-cartilaginous mass greatly enlarged, hard externally, but soft and friable in the centre, contracting both the auriculo-ventricular orifices to a considerable extent. The rings were of the diameter of one's little finger, and the fibro-cartilaginous mass as large as a walnut. Aortic valves healthy.

Lungs.—Both lungs were in a state of passive congestion throughout their entire substance, and the air cells and smaller bronchi full of frothy mucous. There was no tubercle nor any pulmonary apoplexy, and the source of the hæmoptysis could not be traced; but it appeared to have been caused by simple exudation from the engorged vessels. The right lung was adherent to the costal pleura in many places.

ABDOMEN.

Liver enlarged and congested.

Remaining organs healthy.

A microscopic examination of portions of the muscular fibre of the walls of the left ventricle and the soft interior of the fibrous rings proved the existence of fatty degeneration of the heart. The transverse striæ of the muscular fibres were generally most indistinct, and a granular appearance usurped their place. Upon the addition of liquor potassæ, well defined oil globules were easily recognised: in the softened substance from the fibrous rings they were very abundant.

Staff Assistant-Surgeon Foster remarks as follows:—This case appears to me to be worthy of record for several reasons.

It is very unusual for men with advanced organic disease of the heart to continue at their duty to within so short a period of the fatal issue; such men are generally unable to undergo any exertion long before the disease endangers life, and are constantly applying at the hospital for relief from such symptoms as palpitation and shortness of breath, which quite unfit them for the more arduous duties of the soldier's life.

The co-existence of considerable hypertrophy with fatty degeneration appears at first incompatible; but an analysis of the case will, I think, lead to the belief that the softening was a secondary disease occurring to a heart which had been previously hypertrophied by the unsoundness of its mitral valves. In any case, it is a complication which deserves mention on account of its rarity.

But, after all, the disease of the mitral valves was not of sufficient extent to account for the great hypertrophy of *both* ventricles, or to have caused death, and these results must be attributed to some other abnormal conditions.

The key to the first is undoubtedly to be found in the enlargement of the fibrous rings and fibro-cartilaginous mass, and consequent contraction of the auriculo-ventricular openings, creating an additional and very serious impediment to the circulation of the blood. In the various standard works which I have consulted, very little, and sometimes nothing at all, is said upon this subject, and yet it is evidently one of the greatest importance. Dr. Fuller, in his work on "Diseases of the Chest," says (page 561), "Obstruction of the mitral orifice is comparatively rare;" and (page 562), "Obstruction of the tricuspid orifice is exceedingly rare." The ivory balls used at Netley Hospital would have been of great use in determining the exact amount of constriction which had taken place.

But death was not caused by the valvular disease. The ventricles and arteries distended with congealed blood prove that a sudden and total failure of the nervous system of the circulation produced a fatal stasis, and this syncope was caused by the fatty degeneration of the heart.

The reason that no murmur was detected was probably owing to the extreme feebleness of the heart's action. There must have been a diastolic murmur, and very likely a regurgitant one also, though they were never heard. The date of pulsation is much the slowest recorded, as the heart's beats were counted with the stethescope; in other cases in which the radial pulse did not exceed 24 or 28 beats per minute, it is acknowledged that every alternate action of the heart was imperceptible at the wrist.

CASE 2.—*Rupture of the Aortic Valve, produced by an Embolic Clot.*

Private S. K., 27th Inniskillings, was admitted into the regimental hospital at Hazareebagh, on the 14th October, 1866, suffering from a well-marked form of bilious remittent fever. Two exacerbations occurred during the 24 hours; the greater commencing at noon and lasting six hours, the lesser one from about 2 A.M. till 6. Quinine was prescribed in five grain doses three times a day, but without any good effect, and on the 20th he was so weak and hectic, that bark and ammonia were substituted, and brandy administered. On the 27th the paroxysms were less severe, but he remained very weak, and citrate of iron and quinine was ordered. No improvement followed this treatment. He had no sleep for three days, and this rendered large and repeated doses of opium necessary.

Oct. 30.—Liq: potassa arsenitis ℥ x., quiniæ gr. iij.; aquæ sulph. camphoræ ℥j., every four hours. Tinct. opii ℥j. immediately, to be repeated if necessary.

31st.—He slept a few hours after a second dose of laudanum. Takes no food at all, and is very much reduced in strength; to have beef-tea and brandy injections per anum. Pulse quick, but thready, and very compressible.

Nov. 1st.—Pulse not so quick, but still very small; the feverish exacerbations are now indistinct.

2nd.—He no longer retains the injections which, for the last two days, have been administered every four hours, and suffers from profuse perspirations. Omit medicine, and give him tinct. ferri perchloridæ ℥ xxv. aqua ℥iss *ter die*. During the day he seemed stronger, and at 3 P.M., was sitting up in bed conversing with his attendant, when he suddenly fell back, and, after a few struggles, expired.

Sectio cadaveris, 16 hours after death.

Head.—Considerable vascularity and opacity of the arachnoid.

Brain healthy.

THORAX.

Heart.—Six or seven ounces of serum in pericardium; the heart was large and firmly contracted, its muscular walls being very thick and powerful. The left ventricle contained several small fibrinous clots, adhering to the columnæ carneæ; and immediately below the commencement of the aorta, was a large irregularly shaped mass of fibrine, the size of a walnut, adhering intimately to the ventricle and almost occluding the orifice. One of the semilunar valves was torn away from its attachment for fully three-fourths of its extent, forming a loop through which a portion of the clot projected into the aorta; there was also a ragged wound on the wall of the ventricle (not penetrating it) just below the rent.

Lungs healthy.

ABDOMEN.

Liver enlarged and soft, being easily broken down between the fingers. Gall bladder shrunken and quite empty.

Spleen, twice its usual size, and darker coloured, and more forcible than normal.

Remaining organs healthy.

Staff Assistant-Surgeon Foster remarks upon this case:

"This lesion I believe to be unique. The manner of its occurrence is evident. The clots within the ventricle owed their formation to the combined effects of a superfibrinated blood (the result of the fever), and a very weak circulation; the larger one becoming partially displaced, at once arrested the onward flow of the blood, and the violent effort of a naturally powerful heart to overcome the obstruction, drove it firstly into the wall of the ventricle, and then through the semilunar valve.

"The cause of embolism is an interesting subject, and I thought that the astringency of the tincture of iron might have assisted to produce it in the present case; but the firmness and general appearance of its adhesion together with its size, seemed incompatible with any very recent origin. It must have grown gradually, and the feebleness of the heart's action enabled it to gain dimensions, which, in the same position, and under other circumstances, would have been impossible."

Literature.

NEW EDITIONS.

THE literary activity of the profession during the past year may be judged of by the fact that no less than 121 medical and surgical works were issued in the United Kingdom. Some of these, indeed, may be of little value, and others, which the profession would scarcely care to recognise, may be enumerated in the return. On the other hand, many works classified under other heads, especially perhaps the 133 on science and natural history, are undoubtedly the productions of medical men, so that we have contributed a fair share to the 4144 books of all kinds published during the year.

Our own columns have frequently born testimony to the value of many of the productions of our brethren, but with all our endeavours we have found it difficult to keep pace with authors and publishers, and many books have accordingly remained unnoticed.

A considerable proportion of these are new editions, and we therefore propose in this article to dispose of some of them.

The first to claim attention are two splendidly illustrated volumes in their fifth and sixth editions respectively, both complete standard works by authorities of many years experience in their respective departments, both containing all that is necessary for the student or practitioner on these branches of practice, and both published by Messrs. Churchill, and illustrated in a manner even they may be proud of. If there is one thing we could suggest it would be that, of such handsome volumes, the edges might have been cut, but as many, after well studying, will re-bind them, this may be of less consequence than in works of less sterling value.

Having said thus much, we shall be expected to devote a word or two to each. Let us take first Mr. Wilson's,* which is a complete system of cutaneous medicine, and which supplies us with the latest views of one who has held the foremost place in this branch for many years. As Hebra fully acknowledges, British dermatology has always been up to the mark since Willan and Bateman gave it the position it has held since their time, and the mantle of those worthies has unquestionably, fallen upon Erasms Wilson, who has, almost alone, for more than thirty years, sustained the claims of this branch of our art, and kept its scientific progress in our country on a level with, or in advance with it abroad.

The first edition of the work before us appeared in 1842, and at once took rank as the best treatise on the subject. We need scarcely say that the author has taken care, by careful revision of the successive editions as they have been called for, to maintain his reputation, and that this—the sixth—is brought down to the present time in every detail. One of the principal subjects of a work of this kind will necessarily be classification. Mr. Wilson has now adopted what he calls the CLINICAL classification. His plan is to take the most common example of skin disease (eczema), study it in all its various aspects, and gorup with it all diseases "linked with it by natural affinity." He thus creates his first class—eczematous affections.

In this way twenty-two groups are made to comprise every form of disease of the skin and its appendages. Besides precision of classification, Mr. Wilson, as we think very correctly, attaches great importance to accurate nomenclature. He would lead us back to the origin of the several words in common use, and thus enable us to see what meanings were attached to them by the fathers of medicine, and no more useful task could be undertaken, for in such a way alone can ancient authors be understood, much less rendered valuable, to modern thinkers. But we must give a few more details as to the plan of the work. It gives successively the anatomy, physiology, and pathology of the skin. Then a complete system of therapeutics, as applicable to cutaneous diseases. In aid of the practical department we are furnished with a "Formulary of selected remedies," forming a complete pharmacopœia for this branch of practice, pp. 882 to 900. After this we have seventeen pages of a glossary of terms, tracing each to its origin, and full of much classical lore. It cannot fail to be useful. We ought, perhaps, to mention that there is a copious index, so that altogether there are 931 pages in the volume, besides those explaining the plates. These plates are sixteen in number—seven plain and nine coloured. The former, merely illustrating form, are drawn by the author; the latter are faithful illustrations of diseases. To commend the book as a whole would be superfluous. It is worthy of the reputation of the father of modern British dermatology.

The second work of which we have already spoken, is an equally complete treatise on another branch of our art, that of obstetrics, and considering the large part of the profession occupied in this department of practice, and the great responsibility attending, it may be looked upon as even more important than the one already noticed. The name of Ramsbotham has been intimately associated with midwifery for two generations, and the present edition (the fifth) of the son's valuable treatise,* is worthy of the vast experience and untiring energy with which he has maintained the name his father made. Speaking of the father reminds us that the son, the author of the volume before us, has seen long service in practice, and has long been before the world, as an obstetric physician, and as an author. The first edition of this work was, in fact, commenced in monthly parts, some eight and twenty years ago, from which time the several editions have been successively revised by the author. Since then he has held the offices of Physician to the Royal Maternity Charity, and Obstetric Physician and Lecturer on Midwifery and on Forensic Medicine at the London Hospital. The lectureships he only resigned last year, when Dr. Head, his successor, as Obstetric Physician to the Hospital, was appointed to the chair of Midwifery, and Dr. Prosser James to that of Forensic Medicine. Like many a worthy predecessor, length of service told upon him, and feeble health was the cause of his retirement. Among the thousands familiar with these pages, and we say thousands advisedly, for it appears that of the four previous editions, eight thousand copies have passed through the hands of the publishers, to say nothing of several American reprints, not a few will regret to learn that the present has been corrected upon the sick bed, with no other assistance than such as could be afforded by the author's son, who also acted as a nurse. It would be hard, indeed, were such an apology not sufficient for any misprint that may have crept into a bulky volume of more than 750 pages of letterpress. Let us hope, at least, that the author may not be a true prophet when he says, by way of parenthesis in his new preface, that "in all probability this will be the last edition I shall have to superintend." The writer, to whom the Editor of the MEDICAL PRESS AND CIRCULAR has entrusted the duty of announcing this new edition, cannot refrain from wishing that the author may, in his own case, have formed too gloomy a prognosis, and that a period of restored health may enable him to revise other editions as carefully as the preceding ones. This volume is associated with the earliest professional studies of the writer, who was, in fact, at one time a pupil of the author, and who may, therefore, be believed to be familiar with its contents. It is, however, as already stated, so well known as a standard authority on the principles and practice of midwifery, that little need be said except to state the fact of the new edition being ready. We may mention some of the improvements and changes. Another steel plate and two more wood-engravings have been added, raising the total number of illustrations to 171. Of these, no less than 92 are fine, large, steel plates. Two of them contain 13 figures, illustrative of the *corpora lutea*, and are also coloured.

* On Diseases of the Skin, a System of Cutaneous Medicine. By Erasmus Wilson, F.R.S. Sixth edition. J. Churchill and Sons.

* The Principles and Practice of Obstetric Medicine and Surgery. By Francis H. Ramsbotham, M.D., F.R.C.P. London: J. Churchill and Sons. 1867.

Dr. Ramsbotham has added a chapter on the "Diagnosis of Pregnancy," and thus filled up a rather important *hiatus* in a work of this kind. By no question is a busy practitioner more likely to be puzzled and annoyed, and in cases which will turn up in practice he will naturally refer to the obstetric authorities in his library. We have experienced this ourselves, and would willingly see this chapter even extended.

We find here reprinted Dr. Ramsbotham's powerful summing up of his objections to the use of chloroform in *natural* labour. To this he has, however, appended a paragraph or two confessing the very considerable change of his views that further experience has induced. The fact that "the casualties that have resulted have been astonishingly few," seems to have had its due weight with our author, who now recommends the use of chloroform in instances in which he would at an earlier period have discountenanced it, and he now admits that much suffering may be alleviated by putting the patient *partially* under its influence, a practice which the writer, like many others, has for years followed in natural labour with the best effect. With these changed views, although we are not surprised at the desire to record what his feelings on this subject formerly were, we should have been pleased to have had Dr. Ramsbotham's later impressions more fully recited. It may be that he thinks his opponents have fairly answered some of the objections he formerly urged, and that his views having changed, the mere reference to experience and candid recanting would suffice. We must, however, confess that some of the arguments were altogether mistaken, or are now in full force. As an instance, we may mention stigmatising the state of anæsthesia as drunkenness. Does the author admit that this was incorrect, or does he perceive that, even if it were, there would be no immorality in inducing it for beneficent purposes? Again, will he admit that they were right who said chloroform prevented the shock of labour, although he once said shock was more likely to be induced by anæsthetics. Moreover, the completeness of Dr. Ramsbotham's conversion will not be satisfactory to many, for although pronounced in the text, there is a foot-note mentioning the larger mortality from puerperal fever in Scotland than England, pointed out by the Registrar-General, and to this is appended the following question:—"Is it not possible that it may depend on the almost universal employment of chloroform in labour, throughout Scotland, which is rarely used in England?" We look to Sir James Simpson and his many pupils and admirers to reply to this challenge. For ourselves, we are too satisfied to find such an authority as Dr. Ramsbotham coming round to the view we long since adopted to cavil with him on this point.

There were some other points we should have liked to have discussed had space permitted. As it does not, we will content ourselves with saying that in it student and practitioner will find every point treated with the hand of a master, and in a style that is very agreeable to read, while its price is so low, considering what it is, that even with a large sale, outsiders may well wonder how the publishers make it pay. Every one who practices midwifery ought to possess Dr. Ramsbotham's work.

We have now to introduce a much less extensive work on obstetrics,* but one which, in the place it aims to fill, is most valuable and trustworthy. Dr. Swayne, of the Bristol Medical School, completely succeeds in his object to furnish the student with a brief and practical guide on his commencing to attend midwifery cases. It is evidently the result of much experience of the needs of the young student, and shows him exactly how to fulfil his duty without rashness on the one hand, or ungrounded fearfulness on the other. The little volume abounds in useful practical hints. It is divided into three parts. The first treats of the management of natural labour; the second of cases which the student may undertake without assistance; the third of cases in which the student ought to send for assistance. The book is not intended to be a substitute for a systematic treatise on midwifery, but as a simple guide for the beginner. We would advise every medical student to master its contents before undertaking his first case, and if midwives possessed the information it contains, and were guided by its rules, we should unquestionably have more favourable results from their practice.

A second edition has appeared of a well-written little essay† on the morbid poisons, their natural sources, effects, migrations, and the means of limiting their noxious agency. The author, Dr. James Morris, is a disciple of Dr. Lionel Beale, whose doctrines he believes "form a landmark in the history of our science." This second edition is considerably enlarged, and in our opinion improved. Nor can we consider it uncalled for—since, although the labours of Dr. Beale have been carried out with the utmost patience and perseverance, we have reason to think there are numbers who are still, to a great extent, unacquainted with his views. We therefore welcome this readable exposition of them, and would advise those anxious to understand them to peruse Dr. Morris's essay. This is not the place to attempt an exposition of the theory held by Dr. Beale, and as Dr. Morris has furnished us with a summary in his little book it would be quite unnecessary. We may, however, fairly remark, that any one who does not know what is meant by Germinal matter, or is unacquainted with what Dr. Morris calls the "contact theory," ought not to flatter himself that he knows anything about contagion, but should at once set himself to the task of supplying the deficiency of his information.

* Obstetric Aphorisms, by J. G. Swayne, M.D. 4th edition. Illustrated. 1867. Churchills.

† Germinal Matter and the Contact Theory. By James Morris, M.D., London, F.R.C.S., &c. Second Edition. 1867. (Churchills.)

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 15, 1868.

EAST-END DISTRESS.

LONDON is the place where everything attains its largest proportions. Be it good or be it bad, it is all the same in this respect—London shows it to its fullest extent. Its population exceeds that of any other city in the world. The capabilities of merchandise display themselves here on the widest scale, proving that a man may die a millionare, nay, more, may realise means equalling, if not surpassing, those of royalty itself. Crime raises its giant head and stalks through the length and breadth of the community, and poverty, too, assumes its most frightful dimensions in the capital which boasts of being the richest in the world.

This latter feature of the London population is most self-evident at the present moment, in the different parishes at the "East-End." It would be too much to hope that this evil can ever be totally eradicated from human society. However prosperous a nation, or wise and paternal its government, so long as human nature remains what it is, and the world is perpetuated on its present basis, there must be "the poor"—men in actual need, unable to procure for themselves and their dependants the necessities of existence, and who must perish but for the aid of others. The question is only one of extent. The disease is hereditary. Can we do anything to check its progress and bring it down to the lowest point of necessity, where it baffles all our care, and where perhaps it may become an ingredient in the body politic contributing to the general health? We are far from having reached such a desirable state of things yet. Pauperism and distress in the localities referred to are fearfully on the increase, and it becomes more than ever the bounden duty of those in authority

to search into the cause, and, if possible, apply the remedy.

For a long time past it has been evident—more so of late—that our present Poor-law system has hardly been able to cope with the ordinary condition of the poor, much less to contend with those outbreaks of distress, which at times, from unexpected causes, overwhelm multitudes of our fellow-men. Private charity has invariably come to its aid in such cases; but, notwithstanding all—though unknown thousands of pounds have been cheerfully contributed and dispensed—the pauperism is as predominant as ever. Indeed, it is more extensive, and the cry of distress far louder than the winter before. It seems to grow and increase by the very means which are employed to prevent it.

Evidently there must have been something wrong in the administration of the funds so generously supplied, as well as defect in Poor-law management, or the evil would not be increasing with the increase of the means to prevent it. Money in the civilized world is the panacea for want and woe. It can procure whatever is required for the alleviation of men's physical necessities, and when it is forthcoming in sufficient amount, and still those necessities augment, there must be defect in some quarter. Far be it from us to say one word which would have the effect of restraining the liberal donations of the charitable for the relief of the suffering poor, and the rescue of those who have been overtaken by calamity, or ruined by commercial depression. We rejoice to think that there is such a spirit of kindness abroad, and that it pervades almost every order amongst us—that the shilling of the humble tradesman is given as willingly as the sovereign of the wealthier class in every time of need. But still it ought to be borne in mind that the best intentions and the noblest efforts may be perverted, if not judiciously carried out. Money-giving, though praiseworthy and indispensable, is not all. A just distribution of the alms is as much a part of true charity, as the free and open hand loaded with gold, and the neglect of it may lead to consequences as unhappy almost as poverty itself. Some disclosures have already been made, and the subject has aroused the attention of the East-end Committee. Great difficulties, we are aware, attend the proper distribution of gratuitous relief in a locality so extensive, and so thickly populated as the one in question. But we trust that while the truly necessitous are properly cared for, no effort will be spared to prevent a permanent pauperism from establishing itself in the place of a temporary distress, and entailing upon us evils which we may have bitterly to repent, and which it may take years to overcome.

Notes on Current Topics.

The Public Health.

The deaths registered in London during the first week of the year were 24 under the estimated number. This exceeds the prior week by 191. The actual mortality was 1624. 300 deaths were caused by zymotic disease. The average number for the week is 354. Scarlatina was fatal to 43, measles to 55, whooping-cough to 52, typhus to 40. To small-pox 22 deaths were due.

Among chest diseases there were registered 157 deaths from phthisis, 232 from bronchitis, 104 from pneumonia, and 84 from disease of the heart.

The annual rate of mortality in the large towns of the kingdom was 28 per 1000 persons living. The rate in London was 27, in Edinburgh 23, Dublin 32, Bristol 23, Birmingham 30, Liverpool 32, Manchester 40, Salford 33, Sheffield 22, Bradford 32, Leeds 27, Hull 27, Newcastle-on-Tyne 29, Glasgow 27.

Middle-Class Lunatics.

Dr. Ellis, of St. Luke's Asylum, in a letter to the *Times*, draws attention to the fact that there are no institutions for the reception of the insane of the middle classes, and thinks it desirable that a suburban asylum should be built for them. Dr. Sheppard, of Colney-hatch Asylum, supports the proposals, and says that he is frequently obliged to tell applicants that the magnificent institution to which he is attached is only a pauper asylum for the County of Middlesex.

It may well be that between the pauper and those who can afford accommodation in private asylums, there are many whose cases require skilled attention. We believe that in some counties they may be received into the county asylum at a moderate charge. Other cases are, no doubt, under the charge of medical men in country districts. Still, it is worth while to consider whether anything could be done in the matter, although we are at once confronted with the difficulty that an enterprise of the kind ought to be at least self-supporting, and if at all remunerative, would be sure to be carried out. We do not feel at all sure that there is any urgency in the matter. If private asylums were to make more widely known amongst medical men the lowest terms at which they can give moderate accommodation, we believe they would have many more applications than they now meet with. Our opinion on this question is confirmed by the fact that an attempt to erect a middle-class asylum a few years ago fell through for want of funds, although advocated by the leading alienist physicians of the day.

London—Street Accidents of the Past Year.

The Registrar-General's returns give some insight into the sad waste of human life by the so-called accidents that are constantly occurring in the crowded streets of the Metropolis, through carelessness or recklessness. We are told that during the year 1867 the deaths of 164 persons who were killed by horses or carriages in the streets were registered. 49 children under the age of 10 years, 15 young persons from 10 to 15 years of age, 41 persons aged 20 and under 40 years of age, 29 aged 40 and under 60, 27 aged 60 and under 80, and 3 aged 80 years and upwards lost their lives, in many cases it is to be feared from the negligence of men driving in the streets. The large number of children who were killed is accounted for in some measure by the absence, in the poorer parts of the metropolis, of open spaces or playgrounds available for recreation; for children living in crowded and ill-ventilated courts can only play in the open streets. Besides the unfortunate persons killed, a much larger number receive serious injuries, which tend to shorten and embitter the life they would otherwise enjoy. It would diminish the danger of the streets, if light bridges were constructed over, or subways under, the most dangerous parts of crowded thoroughfares; and if the penalties for furious driving were strictly enforced.

10 persons were killed by horses, 3 by carriages, 7 by omnibuses, 17 by cabs, 32 by vans or waggons, 5 by drays,

43 by carts, and 47 by vehicles not described. The large proportion of fatal cases occurring from injuries caused by vans, waggons, and carts probably arises from those heavily laden vehicles being driven so fast that their weight and momentum prevent their being stopped in time for foot-passengers to escape. Cabs and light carriages are more under the control of the driver; hence fewer casualties from this class of vehicles are recorded.

The Medico-Political Association.

This Society, to which we have previously drawn attention in our Irish edition, held, last month, a very successful meeting at Brighton.

The Association has been formed for the purpose of discussing and taking action upon the various questions relating to the position and influence of the Profession. It aims, first of all, at the representation of the registered practitioner upon the Council; and as a second object, at the annihilation of unpaid and under-paid professional labour.

All our contemporaries have spoken a few words of encouragement to the promoters of this Society, and expressed their belief that its objects will meet with the sympathy and approval of the whole Profession. Should the wishes of the Association be realized, it cannot fail to elevate the profession.

The Title to a Prescription.

The *New York Medical Record* publishes a legal opinion on the query whether an apothecary is at liberty, on the request of a customer, to dispense a repetition of a prescription without a special order from the Physician, and argues that he "has no more right to do so than a merchant would have to deliver on a written order for one barrel of flour, sundry barrels after the one called for."

However advantageous for the Profession it might be that a patient should be obliged to return to the physician whenever he required to have his medicine renewed, it would be ridiculous to set up a claim founded neither on practicability nor justice, for a parallel like that drawn by the *New York Record* displays only obtuseness of comprehension in the pleader. A merchant does not deliver several barrels of flour when only one is ordered, because his customer desires only one. If he wished for more he should have them just as he should have three or four bottles of medicine. He buys, as it were, the copyright of the prescription, as regards its application to his own case, for the fee which he pays the doctor, and he has as much right to an indefinite repetition of it, as a publisher has to issue any number of editions of a book which he may have purchased.

It is quite another matter when the Apothecary serves out to all-comers the prescription entrusted to him for dispensing, for, in that case, he has simply purloined the property of his customer, in appropriating a recipe for which he paid nothing—which was entrusted to him in confidence, and for no other purpose than to make it up—and which is in no respect public property. If he does this, he is simply a rogue, and the greater one if he does it under the false colour of his own name.

Water-closets v. Earth-closets.

The last meeting of the Metropolitan Association of Medical Officers of Health was devoted to this subject. The difficulties surrounding the question are aptly illustrated by the differences of opinion that prevailed in an assembly peculiarly qualified to discuss it. Dr. Bishop, formerly of Naples, stated to the Society what it ought previously to have known, that the deodorising property of dry earth is familiar to some Italians, and utilized by them. The President (Dr. Druitt) summed up the debate with considerable perspicuity, drew a broad distinction between the commercial and sanitary aspects of the question, and though leaning to water-carriage for large cities where it is already in operation, looked to the dry earth system to solve the difficulties for smaller communities, as well as for such as may not yet have commenced a system of drainage, or where water-carriage cannot easily be carried out.

A Munificent Doctor.

A meeting of a few gentlemen was held some evenings since, in the magistrates' room at Bolton, for the purpose of entertaining a scheme for the foundation of charities by Dr. Chadwick, of Southport (formerly of Bolton), for poor industrious persons and orphans. The chair was occupied by the Mayor (Mr. Alderman Barlow). Mr. T. L. Rushton informed the meeting that Dr. Chadwick proposed to place £10,000, in railway and other securities, in the hands of trustees, for the erection of three or four blocks of houses in the most salubrious parts of the town, on the best sanitary principles, to be let to poor and industrious persons of good character residing in Bolton, at rents which shall not exceed in any case 5 per cent on the outlay; also to appropriate property in Salford, Stockport, and Harwood, amounting to £6000 or £7000, for the erection of an orphan asylum, in the first instance for girls, and afterwards, when the funds permit, for boys, who reside within the area of the Bolton union. The percentage arising from the rents of the houses is to be devoted to the maintenance of the asylum. The generosity of the donor excited the warmest gratitude, and a number of trustees were appointed to look after suitable sites for the erection of the houses and asylum. Dr. Chadwick, about a year ago, set apart £1000 for the erection of a new infirmary, and another £1000 for the erection of a museum and library in Bolton. He formerly practised in Bolton, where he was much esteemed for his benevolence towards the poor; and this munificence will make his name remembered by the side of that of Mr. Peabody, whose generosity, some time since, excited the astonishment of the whole country.

As medical journalists, we cannot but rejoice at having to chronicle an act like this. Few medical practitioners accumulate wealth, and it is therefore especially gratifying to find an exception to the rule, which binds most of his brethren to work, thus employing his fortune.

The Clerkenwell Catastrophe.

The Committee of the Relief Fund have published their first report. It embraces a variety of particulars which we have not space to enumerate. The funds have come in well, as is always the case when aid is required to meet any sudden calamity. Putting all sums together, they amount to more than £7000. Whether this will be sufficient to meet all the exigencies of the case, time alone can prove. Seven persons have lost their lives by the explosion. Forty-one, variously wounded, are still in the hospitals. There have been twenty-six maternity cases, most of a very serious character, and "as many as 600 families in the vicinity are suffering," more or less, "from the violence of the shock." We are glad to find that sub-committees have been appointed "to visit, personally, every house and every family, to make enquiry as to the

losses incurred, the cases of sickness or privation, and to relieve all pressing wants." We trust that these precautions will secure the right appropriation of the money so generously placed at the disposal of the committee, so that no one who really needs assistance will be overlooked, and, if further contributions should be wanted, they will be forthcoming in due time.

The Slaughter in the American War.

THE Secretary for War of the American Government, states in his report a few of the statistics of the war casualties. No less than two hundred and forty-four thousand five hundred white men, and thirty thousand negroes met their death from wounds and disease, and two hundred and eight thousand were permanently disabled. Truly a horrible result, and a complete justification of the much despised Peace Society.

It is the lot of philanthropists who aim at great objects, to be considered visionary, and therefore contemptible, but surely a fratricidal contest, ending in the slaying of a quarter of a million of men, and the maiming of nearly as many more, with all the consequent misery of mind and body, and without the gain of not one single advantage, either in the present or future, may easily be conceived sufficient to excite the feelings of persons who refuse to hear of impossibilities where great objects are to be gained.

Cookery Reform.

How is it that it has never occurred to any one that it is a wanton waste of good meat, and, moreover, of good fuel, to plunge a juicy joint in three or four times its volume of water, and then and there dissolve out of it a great deal of its nutritive value? The Norwegians have shown us the way to reform in this respect, and it has been introduced to the British public, specially with a view to the economy of fuel in the Abyssinian campaign, by Captain Warren, and under the auspices of the Society of Arts. The unthought of secret is simply to enclose the meat in an inner close cylinder, without any aqueous addition whatever. As this cylinder nearly fills the outside vessel, a very small quantity of water has to be kept boiling, and an immense saving of fuel is effected, while the soluble nutriment of the meat will be no longer carried off in the pot and thrown into the sink. Captain Warren stated that in the expenditure for fuel alone for the army, a saving of £15,000 a year can be effected. Yet simple as the reform may be, and self-evident in its theory as it is, it will probably take ten years before it is adopted by English cooks, and twenty before it forces its way through the circumlocution office.

The Vacant Coronership.

THE sudden death of Mr. James Bird has caused a vacancy in the coronership for the western division of Middlesex, and caused quite a flutter amongst our medical contemporaries, who seem ambitious to predict who will be successful in contesting the appointment. By all means let us have a medical man as coroner. We have so many times urged the propriety of medical coronerships that we need not say more on the subject. There is no lack of medical candidates talked about, but who will go to the poll seems at present doubtful. A legal candidate is already in the field, so that a division of the medical interest may lead to an unfortunate result. We hope, therefore, that the claims of those coming forward will be amicably settled, and the whole influence of the Profession brought to bear at the election.

We have heard that Dr. Hardwicke, Dr. Whitmore, and Dr. Holt Dunn are quite in earnest. Moreover, it has been proposed to invite others to stand, amongst whom we may name Dr. Letheby, Dr. Richardson, and Dr. Odling. So much gossip is afloat that it is not worth while to mention others. All we say is, let the Profession unite to support its man and carry him.

Cost of aintenance in London Workhouses.

THE old saying that "those who will not work shall not eat," seems reversed in London, for the *Pall Mall Gazette* has shown that the living of those who are lodged in the Holborn Workhouse, is very superior to that which many labourers and their families enjoy. Each pauper costs to the Union for food and clothes alone, 4s. 10d. a week, or 19s. 4d. for four persons, while a labourer with a wife and a couple of children gets only about 17s., and has to keep a roof over their head, which in London is no easy matter. The conclusion is obvious—either the pauper is over-fed, which our experience of Workhouses renders highly improbable, or else his maintenance costs relatively a great deal more than that of the working man, a much more likely explanation.

WE have to announce a fatal accident to Dr. Swift, of Eccleshall, near Stafford. On the evening of last Monday week, while returning home on horseback, on account of a hurdle having been placed across the road, the horse stumbled, and the unfortunate gentleman was thrown with such violence as to dislocate his neck. It was some time before he was discovered and carried home.

THE Metropolitan Free Dormitory Association affords shelter, and so, a chance of obtaining employment to many poor women who are literally homeless in the great city. The Society has only started about nine months, but has already afforded a refuge to many unhappy women, driven by misfortune or illness to utter destitution. To save them from a worse fate, this Society steps in with the offer of shelter. Two houses are constantly full, and the committee hope to be able to establish a home in every postal district of London.

MESSRS. LONGMANS have just published the "Story of the Captives" in Abyssinia, by Dr. Blanc, himself one of the captives. We doubt not it will obtain a wide circulation among the members of our Profession.

AS we anticipated, Dr. Tilbury Fox has been elected, without opposition, Physician to the Skin Department at Charing-cross Hospital. Dr. Fox had previously resigned his appointment at St. John's Hospital for Diseases of the Skin, to which last institution Dr. Prosser James has been elected Physician.

DR. PAGE, whose resignation of the Senior Physicianship at St. George's Hospital we announced last month, died at his residence in Gloucester-place, on the 2nd instant. Dr. Page was B.A.Oxon. 1831, and M.D. 1837. He was elected a Fellow of the Royal College of Physicians in 1838, and on the President's chair passing to Dr. Alderson, the deceased Physician became Treasurer of the College.

Address.

INAUGURAL ADDRESS
AT THE
WEST KENT MEDICO-CHIRURGICAL SOCIETY.

By W. LOCKHART, F.R.C.S., President.

GENTLEMEN,—I have to thank you for the honour you have done me in electing me to be your President for the year, and hope to discharge the duties of the office to your satisfaction, and shall endeavour to do what I can to promote the usefulness of our Society.

Associations of this kind are valuable, inasmuch as they give to the members of our profession an opportunity of occasional personal meeting, and thus, further that good understanding that ought to bind us together, and perhaps, in some degree, remove the charge that is often brought against us of being jealous of each others success.

In meetings such as ours we are able to express our opinions on subjects which interest us, and the results of our observations, which would otherwise be lost, are thus made known to each other, with the aim and object which ought ever to be borne prominently in our minds—namely, the welfare and benefit of those who, as patients, commit their health and comfort to our care.

By meeting from time to time we are able to discuss those subjects which arise among the community, often affecting them seriously, and on which, if medical men did not, either by the living voice or by written papers, expound their several views, much would be lost that experience or observation teach us all, whatever be the sphere of our labours.

[The President here referred to the papers expected during the session 1867-8, and then made some remarks on the subjects of interest that have presented themselves in the past year, adding that he had no means of investigation regarding new points but such as are open and common to all.]

One of the things that necessarily attracts our attention is the new *Pharmacopœia* that has lately been issued by the Medical Council. No doubt, many difficulties presented themselves in the production of this work, but the one great object is attained of having one only standard for officinal medical substances and compounds throughout the United Kingdom and its colonies. This is a very great boon. Various new medicines are also now introduced into the list, and the directions for the production of the various medical agents, whether chemical or otherwise, are such as the pharmaceutist can follow and carry out to a successful issue, which is a new feature in official pharmacopœias. The education of medical students is now carried out most carefully, and a high standard required. Care must be taken that the education thus given be not considered so sufficient as to cause the student to suppose he has done all, when he gets his diploma, but rather to lead him to feel that his student life is one that merely fits him to learn his profession afterwards.

In the country with which I have been much associated, and in which I have spent nearly thirty years of my professional life, the education of students for the Medical Profession can hardly be called practical in any sense. There the student, after completing his literary studies, turns his attention only to books; there are no medical schools or means of public instruction. The Imperial College of Medicine in Peking neither teaches nor examines; its officers have only to fulfil certain State duties, and are in part chosen from the most celebrated of the Medical Profession; but even this qualification is not in all cases requisite. A man who desires to take rank in the Profession announces as his most direct appeal to public confidence that he is a Physician of two, three, or four generations. Surgery is almost wholly unknown. The practice both of medicine and surgery is entirely empirical, and it is not so much from the use of drugs that practitioners derive their success as from the dietetic rules and good nursing which they enjoin. It is a remarkable circumstance that so large and populous an empire should possess so little even of the art of physic; and yet its people increase and multiply year by year. I used often to think on this subject when present among the people, and was led to the conclusion that the effect of our European systems, and the practice of medicine and surgery, are not powerful so much in prolonging life, as in rendering that life in its morbid conditions more endurable. In a country circumstanced as China is, eye disease produces great misery, cases of this kind being wholly left to nature, without any effective interference. Small-pox inflicts frightful ravages, more especially in the north of China. Almost one in three persons is marked by small-pox, and many have their eyesight damaged from the same cause. It is true that inoculation is practised, but this, while abating the violence of the disease in individuals, perpetuates it among the community. In cholera epidemics very little is done, and the treatment that appeared to win the confidence of the people in Peking during the fearful epidemic of 1862, when I was there, was the use of acupuncture in the back of the leg. In many cases seen by me at that time, the choleraic poison seemed simply to kill. There was often little vomiting or purging, but cramps and collapse constituted the condition of the patient.

Our own land suffered much last year from cholera, but happily we have had no fresh visitation of the disease in an epidemic form, though it would appear that some accidental or sporadic cases have occurred. The same thing prevails in the East. There is seldom or ever a year passes by in which individual cases of well-marked distinct cholera do not present themselves, and yet the disease does not spread; while in other years the whole community is more or less affected.

The President next alluded to the subject of treatment, and the fact that the early cases of an epidemic are usually fatal.

He next offered some remarks upon the connection between the presence of ague and the absence of lung disease in districts where the former prevails.

He then continued—A very remarkable disease presented itself in Ireland during the early part of this year—that form of cerebro-spinal meningitis, which was called febris nigra, or malignant putrid fever, also noticed in Germany for some years past. I was present at the meeting of the Royal College of Physicians in Dublin, when the subject was discussed. The cause of the fever is hidden in obscurity, but the effect seemed to be a poisoning of the blood, which, in the early and most fatal cases, ended in large parts of the body being perfectly black. The general feeling, which was participated in by Dr. Stokes and several others, was that it is non-infectious. Happily the disease has not visited us in England thus far.

While we have, by God's good providence, been spared the visitation of plague and pestilence, we have heard with feelings of sorrow the terrible visitation of fever in the island of Mauritius, which has been exceedingly fatal. It would appear to have been a malignant form of intermittent fever, partly caused by the cutting down of the forests in the interior, thus disturbing the equable seasons of the country.

In the southern parts of the southern states of the United States, as in Texas, there have been, and still are, frightful ravages committed by a very fatal form of yellow fever, so malignant in its character, that we happily have no experience of such in this country.

While speaking of infectious diseases it may be remarked that in the East measles are usually little known, and scarlet fever hardly if ever seen. Of late years there appears to have been an increase in the cases of small-pox in England and other parts of Europe; and it is a remarkable fact, that in the navy (and this applies to other navies as well as our own), the men are very liable to small-pox, so much so, that it would appear as though the presence of many persons sleeping and living together for long periods, gives rise to the disposition to this essentially purulent disease. In connection with this subject I would throw out the query about pus—is it in the blood or is it produced as a result of change in the structure of parts?

Sewage of towns, difficult to dispose of, but when the greatest judicious care is taken, then also, in all instances, is the death-rate of the inhabitants diminished. As, for instance, in several of our large towns, and notably in Liverpool, of which town I am a native, and was once dispensary surgeon, during epidemics of typhus and cholera, in 1834. Well do I remember the fearful ravages of these diseases in the lower parts of the town, but which now are becoming more salubrious. In my opinion, though I speak quite impartially, having nothing whatever to do with the parties concerned, I believe the dry earth closet system is the best for the disposal of sewage. I had the opportunity of witnessing it in operation in Dorchester, some time ago, and was astonished at the complete effect of the system. Excuse my frequent reference to China, but I there saw largely practised a similar thing, where the manure gatherers collect the night soil, mix it with earth, dry it in the sun, and export it in the form of inodorous *cakes or bricks*, which are *afterwards* mixed with water and scattered over the fields.

The subject of Medical Coroners is very important, and it

seems strange that the self-evident desirability of a medical man in such an office should not be recognised. The president here mentioned that inquests are held in China, and that the coroner is always a medical man, who goes with the magistrate to examine the body of the deceased person. He said he had been present at one of these inquests held in his hospital, and witnessed the examination of the body. He here showed Chinese work on inquests. He then referred to the Papers on Mankind, read at Dundee, and alluded to some remarks of lecturers on Unity of Mankind. He then criticised Curious Researches of Dr. Bence Jones, on opalescence of animal tissue, probably from presence of quinine in the tissue, which malaria probably destroys, and referred to other subjects of late before the profession, including the Laryngoscope—the Ophthalmoscope—Sygmograph—the use of Thermometer in observing Temperature in Disease—Acupressure—Treatment of Cancer by Injection of Acetic Acid—Local Anæsthesia—Reduction of Dislocation by Manipulation—Cure of Aneurism by starvation, acetate of lead, compression, and introduction of wire.

The President concluded by mentioning the deaths in the profession during the year—among others, mentioning, with respect, Sir Chas. Hastings, Sir Wm. Lawrence, Trousseau, Velpeau, Brinton, Jeaffreson, Barlow, Toynbee of the Medical Benevolent Society, and Propert of the Royal Medical College at Epsom, observing that to the two latter the thanks of the Profession are especially due, for their untiring and benevolent exertions on behalf of the widows and orphans of medical men left unprovided for.

DR. LETHEBY ON THE PROPAGATION OF CHOLERA.

In his report on the sanitary condition of the city of London for the year 1866-7, just issued, the learned and indefatigable Medical Officer of Health for the City gives an able and elaborate account of the last epidemic of cholera, and examines some of the theories that have been propounded to account for the sudden outbreak of the pestilence. Constant readers of the Medical Press and Circular will not require to be informed that it has long been known that Dr. Letheby entertained grave doubts as to the truth of that theory which attributes the spread of cholera to pollution of the drinking water—a theory which, from its nature, might seem to superficial observers fully satisfactory, and which has been forced upon the public with unusual pertinacity. It is natural, therefore, to turn over the leaves of this report, and see first what will be said by so competent an authority on the question.

Let us, then, at once state that Dr. Letheby gives no countenance whatever to the water-theory. Not that he thinks it necessary to deny that the contamination of water by choleraic excreta or other impurities might in some cases generate disease; but he finds that the hypothesis of the distribution of polluted water being the cause of the spread of cholera is insufficient to account for the facts of the last epidemic.

It is needless to observe that any hypothesis which does not account for *all* the facts is by that very circumstance provocative of doubt; while the moment *any* of the facts are shown to be irreconcileable with it, it must be abandoned.

For a long time the advocates of the water-theory have had the ear of the Profession and the public, and they have been instant in season and out of season, in proclaiming its sufficiency. It is time, therefore, that those who feel dissatisfied with it should have a hearing, and if they have waited patiently for a leader to express their views, it must be acknowledged that they now have one with whom it will require all the forces of the opponent to cope.

The gauntlet has indeed been thrown down before this, but the upholders of the water-theory have been too ardently engaged in trumpeting their one idea, to pick it up or to notice the evidently hostile but silent and dissatisfied investigators, who were not carried away by their enthusiasm. In these days of sensationalism, we may well feel some content at the calm which reigns over so large a part of the professional mind, and moulds it into a patient waiting for truth, which is often mistaken for incredulity. This saves us from that instability which would make us a prey to every wind of doctrine, and enables us to preserve the expectant attitude with which alone we may hope to successfully interrogate nature.

The Medical Press and Circular, during the last year, has devoted much space to an examination of the various theories that have been submitted respecting cholera. It becomes us, therefore, at once to give prominence to the views expressed by Dr. Letheby. We therefore hasten to lay before our readers, in his own words, the salient features of his report, merely bespeaking for them the attention that is their due, and calling upon the advocates of the doctrine thus impugned, to substantiate their views by a full reply, or to acknowledge that they are henceforth untenable.

After a succinct history of the epidemic, embracing a notice of some of its prominent features, and a brief allusion to some other theories, Dr. Letheby thus comments on the hypothesis that polluted water was the source of the mischief :—

The alleged pollution of the water rests upon a series of assumptions, many of which are in the highest degree improbable. It happened that two deaths from cholera occurred on the 27th of June, at Bromley, immediately in the neighbourhood of the East London Water-works, though far removed from their source of supply ; and it is assumed that the alvine discharges of the two sick persons were cast into the privy, and found their way, through the sewers, in the river Lea, where, by being diffused through a large volume of water, they passed upward against the current of the stream, and arrived opposite an open, but rarely used, reservoir of the water company ; that they then soaked through a thick embankment, and so obtained access to the water of the uncovered reservoir ; that on a certain day some of this water was admitted into the covered reservoir, from which the public supply was taken ; and that it was thus distributed to the district supplied to the company. But if, for the sake of argument, it were admitted that all this did in reality happen, it would be a curious mathematical problem to determine what was the degree of final dilution after the alvine matters had entered the sewers, then the river Lea, then the open reservoir, and, lastly, the covered reservoir ; for it is not supposed that the choleraic discharges were bodily conveyed to the covered reservoir, but that only a small portion of each of the successive dilutions became mixed with larger and larger volumes of water.*

Apart, however, from the improbabilities of these assumptions, it is a fact that the water which is said to have been thus polluted did not produce its effects in the several districts to which it was distributed in anything like uniformity of time or force. Suppose, by way of illustration, that alcohol or arsenic had become mixed with the water, and that on a certain day it was distributed to the public, we should expect to find that the action of the poison was not only manifested at the same time over the whole district of supply, but that it was confined to that district. Not so, however, with the water in question, for although it is not alleged to have been more than once polluted, yet the first effects in the several districts occurred at long intervals ; and there were many places to which it was distributed, where there was no sign of the disease ; while others which did not receive the water were seriously affected.

The dates of the outbreak of the disease in the districts supplied with the East London water, were as follows : Bromley, June 27th ; Poplar and Bethnal Green, June 30th ; Shoreditch and Mile End, July 7th ; Whitechapel, Stepney, and St. George's-in-the-East, July 14th ; and the East London Union, July 28th. A month therefore elapsed between the first outbreak of the disease in the several districts. It is, moreover, remarkable that, while it was so violent in many of the districts of supply, it was absolutely powerless in others. The death rate for example of Bethnal Green was 63 per 10,000 of the population ; Whitechapel, 78 ; Poplar, 85 ; and St. George's-in-the-East, 93 ; whereas the districts of Stamford Hill, Upper Clapton, Walthamstow, Woodford, Wanstead, Leytonstone,

* I need not discuss another supposed source of pollution, the cholera cases at Theydon Bois, eleven miles from the works, for that hypothesis is abandoned.

Buckhurst Hill, North Woolwich, and Silverton,[1] were absolutely untouched by the disease, notwithstanding that they received the same water, and at the same time.

More remarkable still, there were places in the very heart of the cholera field, and others close adjoining it, where the residents received the same suspected water, and used it freely, without suffering in the least degree. In the Limehouse School, around which the cholera was frightfully fatal, there were 400 children who drank the same water as their neighbours, and yet there was not even a case of diarrhœa among them. In the London Hospital, which is also in the heart of the cholera field, for it is surrounded by the districts of Whitechapel, Bethnal Green, Mile End Old Town, and St. George's-in-the-East, there was an average resident population of 463 persons, and, although they drank freely of the unfiltered East London water, yet there was not a case of illness among them.[2]

Again, in the eastern division of the city of London, which adjoins the cholera field, the suspected water was supplied to 161 houses, with a population of about 1732 persons, but except in one of these houses (20, Somerset-street), which is on the boundary of Whitechapel, there was not a single death from cholera,[3] and to verify this, I have obtained the addresses of all the persons who died in the cholera ward in Bishopsgate-street. But, besides this, the disease was singularly fatal in places where the suspected water was never used. In Crown-court, Blue-anchor-yard, Whitechapel, where the water supply is from the New River, the mortality was at the rate of 284 per 10,000. In Boar's-head-yard, of the same district, which is also supplied by the New River, the death-rate was 193 per 10,000; and indeed there are eighteen courts in Whitechapel, where none of the East London water was used, and yet, out of an aggregate population of 4351 persons, there were 30 deaths from cholera, the mortality being at the rate of 69 per 10,000; that of the whole district being but 77.

Another such an instance is the case of the City of London Union at Bromley. In the midst of the cholera districts it suffered in common with the whole neighbourhood, for out of 765 persons it lost 27 from the disease, which is at the rate of 353 per 10,000. But during the whole of the time the residents used no other water than that from a deep artesian well, which, on being analysed, was found to be good and wholesome.

So that on carefully examining the facts in their relation to the water theory, we find—

1. That there is no proof whatever of choleraic pollution of the water.
2. That there was no coincidence of time in the appearance of the disease in the several districts supplied with the suspected water.
3. That numerous districts receiving the same water, but situated at high level, or placed beyond the cholera field, were entirely exempt from the disease.
4. That even in the very heart of the cholera field, there were places receiving and using the suspected water with impunity.
5. That other places not supplied with the water, but situated within the infected area, suffered equally with the neighbourhood.

I am far from wishing it to be thought that choleraic matter diffused through water will not produce disease. There is abundant evidence to show that it is often a prolific source of it; but I am anxious in dealing with a question of so much public importance as the origin of the late epidemic, that none of the facts should be perverted, and that no hasty or ingenious hypothesis without solid foundation should take possession of the public mind. In the conduct of inquiries like this there should be a calm, a full, and a candid examination of the facts. We should endeavour to study the phenomena in a philosophical spirit, and apply to them the tests of sound induction; we should strive also to deduce from them such laws as will not only expose the nature of the malady, but will at the same time enable us to treat it successfully. Rash opinions, boldly asserted and tenaciously held, though they may force themselves on public attention, rarely lead to useful results; and while they have their hold on the popular mind they seriously hinder the progress of real knowledge.

1 Silverton was affected towards the end of the epidemic, when no water theory could account for it.

2 574 cases of cholera were treated in the Hospital, but they were all brought into it sick of the disease. A nurse who lived out of the Hospital died of the disease.

3 There were two deaths in this house from cholera, but both were late in the season—viz., one in the first week of August, and the second in the third week.

Looking back, however, on the experience gained by the last visitation of cholera, and comparing it with that of other visitations, we may fairly ask if any general conclusions may be deduced from the most prominent facts. It appears indeed—

1. That cholera is not indigenous to this country, or even to Europe. Its home is the swampy and low-lying districts of India, where, from the year 1817, it has been native to the soil. No other tropical ground is persistently occupied by it; for, although it may visit other such localities, and for a time be severely fatal, yet it never fixes itself endemically in any place beyond the Indian Peninsula. The Delta of the Nile seems at first sight to be as congenial to it as the banks of the Ganges and the Hooghly, but although cholera visits it in its migrations, it never permanently occupies it.
2. That in its journey from India it always follows the lines of traffic, moving from port to port along the coast, and passing inland by the tract of navigable rivers. Until the last visitation its course from India was always the same, but the rapid advance of commerce has changed its route, and made it pass at once from the eastern frontiers of Asia to Southern and Western Europe.
3. That it is always imported into this country from an infected district, and generally from Holland or the ports of the Baltic.
4. That the visitation is not preceded by any remarkable condition of the atmosphere; for although in the epidemics of 1832, 1848, 1854, the weather was warm, the barometric pressure high, the air stagnant with prevalent mists, and there was but little rain, yet in the visitation of 1866, the condition of the weather was almost exactly the reverse of this—for the barometer was generally low, the season was cold, the atmosphere was constantly in motion, with frequent gales, and there was much rain.
5. That although the disease is of tropical growth, and is generally most severe in its manifestations during the summer and autum heat, yet it is not always checked by the cold of winter. The epidemic of 1830 was terribly fatal at Moscow during the winter of that year. The same was also the case at Berlin in 1832; and the epidemic of 1849 was at its height in Glasgow, Paisley, and other towns of Scotland in the middle of winter; so also in the epidemics of 1854 and 1866 the deaths from cholera at St. Petersburg were very numerous when the thermometer was below the freezing point. It may be that the conditions as to temperature and moisture within the houses at this time were not very different from those of summer time.
6. That the advent of the disease is generally marked by some increase as it were of the zymotic force. It is difficult to judge of the general condition of the public health at the time of the visitation in 1832, but at the coming of the epidemics of 1848 and 1853, there was an unusual amount of zymotic disease. At Moscow and St. Petersburg, and in other Russian towns, the outbreak of 1848 was preceded by a general prevalence of influenza, and of intermittent fever; the latter disease, in many continental cities, taking the place of typhus in this country. Diarrhœa also, in the European cities first attacked, was generally prevalent before the actual outburst of the disease. At Berlin intermittent fever, diarrhœa, and dysentery, but especially diarrhœa, were epidemic. The same disease, but particularly intermittent fever, scarlet-fever, and influenza, were prevalent at Hamburgh. In London there had been, during the preceding five years, a progressive increase in the whole class of zymotic disease—amounting to an excess of 31 above the average—the diseases which chiefly contributed to this excess were typhus, scarlet-fever, influenza and diarrhœa.[1] A like increase in nearly the same disease, preceded the epidemic of 1854, as if the public health was below the standard, and the conditions existed for the development of zymotic maladies. Not so, however, at the coming of the last epidemic; for, excepting a very slight increase in the proportion of deaths from typhus and small-pox, there was nothing to indicate an unfavourable state of the public health; said diarrhœa, the common precursor of cholera, was much less prevalent and fatal than usual.
7. That the habitats of the disease are on low and marshy-ground, along the margin of tidal rivers, where the soil is porous, and is sodden with animal excreta and where the population is dense and not of cleanly habits. It has, however, eccentricities of selection; for sometimes it will fix itself on

1 Report of the General Board of Health on the Epidemic Cholera of 1848-9.

one side of a street, and not touch the other; or it will localise itself in one ward only of a prison or lunatic asylum, or workhouse. There is no doubt a sufficient reason for this, but at present its capriciousness passes our comprehension.

8. That when it attacks a place, it always commences with a few straggling cases ; it then rapidly increases in violence, and gradually abates. The circumstances which give intensity to its action are entirely local, as the altitude of the place, the density of the population, and its sanitary condition. The altitude of a place appears to have the largest influence; and next to this the density of the population. In the epidemic in 1849, this was well exemplified by the duration of the disease; for in 41 registration sub-districts, each with a population of less than 10,000, the average time of the epidemic was but 81 days ; in 44 sub-districts with from 10,000 to 20,000 inhabitants, the mean duration of it was 108 days; and 35 sub-districts with from 20,000 to 30,000 persons it was 117 days. But it has its caprices in this respect, for in the three epidemics of 1849, 1854, and 1866, the time of its reaching its greatest intensity in London was 14 weeks, 9 weeks, and 5 weeks respectively; and the duration of the disease was equally variable—the last epidemic remaining with us but six months, while in former visitations it was here for more than a year. The influence of sanitary measures may have had something to do with these results, for their beneficial action has everywhere been abundantly proved.

9. That as regards the individual attacked by the disease, it has been generally observed that he has suffered from diarrhœa for one, two, or three days before the setting in of serious symptoms; and this is ordinarily amenable to treatment.

10. That the period of incubation of the disease—that is the time which elapses between exposure to infection and the coming on of well-marked symptoms is variable, although it probably ranges from three to eight days.

11. That the duration of an acute attack when the symptoms are fully developed is rarely over a day, while that of common English cholera is not less than three days, and of ordinary diarrhœa six days.

12. That the mortality is always most severe at the beginning of an epidemic, when, as in the London Hospital, it may amount to 85 per cent. of those attacked ; whereas, at the end of the visitation, it is much less severe, and may not exceed 37 per cent. Throughout the whole of the epidemic, however, the mortality has generally been from 41 to 50 per cent., excepting when, as in continental cities, the sanitary conditions are unfavourable, and then it may amount to from 60 to 70 per cent.

13. That the disease is only infectious in the sense that the alvine discharges of the sick are capable in all probability of communicating the disease to the healthy. Observation indeed, in every part of the world, leads to the conclusion that they are the sole agents in propagating the disease ; but the exact element or *materies morbi* which is thus concerned in communicating it is not known. The researches of Dr. Parkes in this country, Dr. Thome, of Cologne, Professor Klob, of Vienna, and Professor Hallier, of Jena, have shown that the alvine discharges of persons sick of cholera, contain myraids of low cryptogamic organisms of the nature of a minute microscopic fungus, which is capable of rapid growth and multiplication within the human intestine, and which feeds on and destroys the mucous coat of the bowel. It would seem, too, from the experiments of Dr. Thiersch, of Munich, and of Dr. Sanderson, of London, on mice fed with paper saturated with choleraic matter, that the alvine discharges are not infectious in their fresh condition ; but that after the fourth day, and up, perhaps, to the eighteenth day, they possess infectious power. If further experiments give a conclusive value to these results, their importance cannot be over-estimated ; for it points to the means of at once arresting the course of the epidemic by the quick destruction of the alvine discharges, and of all things that are soiled by them.

14 and lastly. It is unquestionable that active sanitary measures employed even during the visitation of an epidemic, are of the greatest value in checking its course. The differences in the force of the disease at its several visitations to the city afford ample proof of the usefulness of your sanitary measures ; and standing, as the city does, on the confines of the cholera field of 1866, I have no doubt that the active operations which were then enforced prevented the spread of the disease westward, especially along the low lying districts of the river, and thus formed a barrier to its progress.

THE VENTILATION OF SEWERS.

In our notice of the report of the Metropolitan Board of Works, we mentioned that Professor Allen Miller, M.D., F.R.S., had made a valuable report on the ventilation of sewers, and promised to give some particulars of his investigation. This promise we propose now to redeem.

Dr. Miller starts by remarking that the efficacy of charcoal as a deodorizer in the case of sewer gases may be considered as settled. His experiments were accordingly undertaken to ascertain—

1. Whether the use of charcoal trays in the ventilating shafts introduced any serious obstacle to the due ventilation of the sewer; 2. The frequency with which the charcoal would require to be changed ; and 3. To determine the mechanical, arrangements which would be most suitable.

From careful observations it was ascertained that in the twenty-four hours the temperature in sewer of the Avenue-road, Regent's-park, never varied more than four degrees. Further, the total range in a month, even when the external temperature was rapidly rising or falling, never exceeded 8°, excepting in one or two instances after a heavy fall of rain, when the flood waters rose high enough to reach the thermometers.

1st. *Determination whether the charcoal injuriously impedes the ventilation.*

This could be determined by two methods, viz.—*a.*, by ascertaining the ordinary draught of air in the sewer when there was no charcoal, and then ascertaining the amount of draught after the charcoal had been introduced ; or *b.*, by analysing the air before and after the introduction of the charcoal, and ascertaining whether any serious diminution of oxygen or increase of carbonic acid had occurred.

a. The variation of the draught of air in the sewer was examined, as follows :—A puff of smoke was produced by firing a little gunpowder, and ascertaining the time occupied by the smoke in travelling up or down the sewer for a known distance. This method answered its object sufficiently well, but it was found that such slight causes interfered with the strength of the draught, that much less information of value was obtained than had been anticipated ; since the direction of the draught and its amount were liable to be interfered with by local accidents, such as the imperfect closure of a trap, the variable force of the wind, and the opening or shutting of a side entrance : so that the act of entering or leaving the sewer for the purposes of experiment, was more than once found to reverse the direction of the current of air in the body of the sewer during the observations.

So far as the observations go they, however, show that the introduction of the charcoal into the boxes produces a sensible retardation of the current of air. Indeed any other result would be impossible.

Three sets of experiments were made upon this plan; one set before the charcoal was introduced ; and two other sets after the boxes had been charged with charcoal.

The average rate deduced from six experiments *without the charcoal* showed a current moving at the rate of 4254 feet per hour.

The first set of trials, consisting of three experiments, *after the introduction of the charcoal,* gave a current moving at the average rate of 3263 feet per hour, and the second set of trials, also, an average of three experiments, showed a current of 2005 feet per hour, in the same part of the sewer.

b. Effect of the Charcoal on the Chemical composition of the Air.

It was ascertained by direct trial that air passed freely through the charcoal in the trays, but no sewer odour was ever perceived in the escaping air ; though if the box of charcoal were purposely removed from the ventilating shaft, an immediate and powerful odour of sewage was perceived. The charcoal, therefore, did its work in absorbing the offensive products. It had, however, no direct action upon the atmosphere in the body of the sewer ; but, indirectly, it might be expected to impair its quality by detaining it for a longer period within the sewer, thereby causing it to lose a larger portion of its oxygen than if a freer current of air was maintained. The oxygen during its detention would combine with part of the decomposing refuse, whilst an increased amount of carbonic aci d was to be looked for as one of the products of decomposition ; besides which a small quantity of carburetted, and occasionally of sulphuretted, hydrogen might occur in the more stagnant parts

Samples of air were therefore collected for analysis both before and after the introduction of the charcoal.

From an average of eighteen experiments upon the quantity of carbonic acid, made during the month of May before the charcoal was introduced, and before the lateral sewers had been provided with flaps, the average quantity amounted to 0·106 parts per cent., while in the open air, the average may be taken at 0·040 parts. The mean temperature of the air within the sewer during this period was 50°·8, ranging between 48° as a minimum and 56° as a maximum.

The mean amount of oxygen in the air of the sewer was for the same interval, from an average of six experiments, 20·71 per cent., the proportion in the open air being 20·96.

After the introduction of the charcoal, the quantity of carbonic acid was found to have risen to 0·132 parts per 100 of air, the mean temperature in the sewer having risen to 56°·2, with a minimum of 52°, and a maximum of 61°·5.

The average amount of oxygen was 20·79. No sulphuretted hydrogen was present.

As a general rule it was found that the quantity of carbonic acid in the air within the sewer increased in proportion as the temperature rose in the sewer, and it declined again as the temperature fell.

No connection between the fluctuation in the amount of carbonic acid and the variation of the barometer could be traced.

On the whole, the air of this sewer was not seriously altered by the obstruction occasioned by the charcoal.

Another set of experiments were made in the Brompton sewer. The register thermometers were suspended in this sewer on the 3rd of October, and samples of the air in its ordinary condition were taken on the 4th and 5th of the month. On the 6th of October charcoal was placed in all the boxes in the ventilating openings, and samples of the air of the sewer collected as before, for analysis.

An average of six samples of air before the charcoal was introduced showed that the air in its normal state contained the large proportion of 0·307 per cent. of carbonic acid, with a temperature ranging in the sewer between 57° and 60°, with a mean of 58°·2.

During the months of October and November, twenty-four samples of the air were examined after the introduction of the charcoal, giving a mean of 0·251 per cent. of carbonic acid, with a mean temperature of 53°·2, ranging between 49°·5 as a minimum, and 57°·5 as a maximum. The diminution in the proportion of carbonic acid is in no way to be accounted for by the use of charcoal, but is occasioned, no doubt, by the fall in temperature which took place as the days became shorter.

It appears, therefore, that even in a tide-locked and imperfectly-ventilated sewer as this is no serious obstruction to the flow of the air through the ventilators was produced by the charcoal. It should be added, that the proportion of oxygen after the introduction of the charcoal was found, on an average of four experiments, to amount to 20·7 per cent. This sewer was free from sulphuretted hydrogen.

"Dr. Miller remarks upon this—"Although these results appear to show that the use of charcoal is not only effectual in preventing the escape of offensive gases from the sewer openings, but that it also does not prevent any dangerous obstruction to the ventilation, yet the question of the general adoption of charcoal boxes in all ventilating shafts is one of such extent and importance that it cannot safely be decided by experiments upon isolated main sewers such as these.

"The introduction of Charcoal Ventilators not only will require a large outlay, but it involves a possible risk to the safety of the men who work in the sewers. The results appear to me to be such as warrant a systematic trial of the method over a limited area. A complete district, drained by certain sewers, ought in such a case to be included, as it is only under such circumstances that the working in actual practice can be tested. When main sewers only are operated upon, in spite of all the care which can be taken, side draughts must interfere with the results, the flaps get eaten through by rats, damaged by flood waters, obstructed in their working by deposits, and various defects occasion uncertainty. If once a *District*, however, has been properly trapped and supplied with charcoal boxes, these difficulties disappear. It would be necessary to test the composition of the air at intervals. The effects upon the house drains, and upon the men employed to cleanse the sewers, should, of course, be carefully watched."

2. *The frequency with which the charcoal will require to be changed* in the ventilating boxes.

Dr. Miller examined some of the charcoal which had been in one of the ventilators (the lowest point in the sewer) for nearly six months, and found that it contained nearly one-fourth of its weight of moisture, but appeared as though dry when handled. This moisture had been condensed in the pours of the charcoal, and had not penetrated the box from the road. 100 parts of the damp charcoal gave off, when heated, 19·7 parts of water, and a small quantity of an offensive ammoniacal liquid. Nitrates were also found in small quantity in the products retained by the charcoal.

In another, much fouler sewer, where the charcoal had been in use only about ten weeks, Dr. Miller found it still efficient, although in one or two instances, where the traffic is considerable, the mud had worked through the covering, and gained access to the upper layer of charcoal. The lower part of the charcoal was, in each case, clean, and though saturated with condensed moisture, it still effectually purified the air from the sewer, which, as direct trial showed, passed freely through the layer of charcoal.

Another portion of the charcoal after ten weeks exposure in the ventilator of a sewer had absorbed 37·2 per cent., of moisture, and the water which was distilled off had the peculiar and offensive odour of the sewage gases.

The charcoal appeared dry to the touch, although it had condensed so large a proportion of water. The important practical conclusion is that charcoal, though thus saturated with moisture, does not obstruct the escape of air, which it still effectually purifies.

3. *The Mechanical arrangenents best adapted to the employment of Charcoal air fillers.*

In the earlier trials, three layers of charcoal, each about two inches thick, were employed. The charcoal was broken into fragments about the size of cob-nuts, ordinary wood charcoal being used. A bushel of this charcoal weighed 15lb. 2½oz., and the average weight of the charcoal, in the three trays together was 6¼lbs.

Experience showed that some modification was necessary to prevent the road drift from working in; on this account in one sewer a single tray of charcoal, 6 inches in depth, was substituted for the three shallower trays with good effect.

Further improvements, however, might easily be made in the arrangements for keeping the road drift out, and for facilitating the removal of such portions as inevitably must work through the gratings. Such modifications are particularly needed where the traffic is considerable.

In conclusion, Dr. Miller remarks that although these experiments have extended over several months, and no time has been unnecessarily lost, the question of the duration of the activity of the charcoal and its fitness for renewed use if reburned, with several others of considerable practical importance, cannot be decided without a further prolongation of the observations.

Correspondence.

CONDY'S FLUID.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the report by Dr. Procter on disinfectants, which appeared in your number of the 1st inst., there are some observations on Condy's fluid, which appear to me to call for remark.

"Condy's fluid," he says, is an "extremely energetic oxidiser, but practically expensive." To this statement I beg to reply, that among those who use it largely and continuously at, for instance, public departments, Condy's fluid has quite a different reputation as regards cost. In support of this assertion of mine I will quote the following passage from a report to the Vestry of Chelsea by Mr. Alder, the Sanitary Inspector of the Parish:—

"At my suggestion Condy's fluid, during the last three months, has been applied to the purification of the public urinals, which are twenty-one in number, instead of the chloride of lime previously in use. Not only has the cost of keeping them sweet thereby been reduced from three shillings to one shilling each per week, but the superiority of the results has been most remarkable."

Further on in his report Dr. Procter says that it is doubtful whether Condy's fluid "can be relied upon alone for the perfect removal of living matter," basing this remark on some experiments of Mr. Crookes' connected with the cattle plague inquiry. It appeared the latter gentleman had found that when "cheese mites in a foul solution" were

treated with chlorine, the foul matter of the solution was acted on more rapidly than the mites. But it is precisely this rapid and preferential action on offensive decomposing matter, which constitutes the true characteristic of real disinfectants, rather than efficacy in destroying cheese mites and the like. Were mere power to deprive the latter of life to be made the criterion for determining the disinfecting properties of substances, many bodies which otherwise could never be suspected of belonging to the class of disinfectants would be ranked high among them; such, for instance, as tannin and quiniæ, which, according to Herr Binz, are most energetic poisons to infusorial life. It would seem to me, that to kill such organisms without destroying the foul matter which forms their nidus would only serve to provide additional material for decomposition, whereas the destruction of the nidus would of necessity lead to the ultimate death of the creatures whose pabulum it was. There is every reason, moreover, to think that those minute living beings, instead of being causes of the decay of animal substances are but attendants on decomposition. Indeed, Liebig long ago showed (*Chem. of Agric.*, p. 403) that, like confervoid vegetation in water, they are, during their process of life and propagation, sources of the purest oxygen gas; as Pasteur has since (*Comptes Rendus de l'Acad. des Science*, Feb. 17, 1863) succeeded in proving that "the mycoderms, which are concerned in fermentation, have the property of imparting activity to oxygen, and thus of carrying to their ultimate results the decomposition of decaying organic matter, and that in this way they are powerful disinfectants."

It is evident, then, that it is the foul nidus in which low orders of living organisms develop themselves that are to be feared in connection with infection or contagion, and not those organisms themselves. The rise, progress, and decline of such foul matters, are of course due to chemical processes. That the progress of those more specific matters which constitute infection is also under the control of chemical affinity would seem to follow from the experiments of Dr. B. W. Richardson, by means of which he obtained from diseased pus an active morbid principle capable of entering into various combinations like purely chemical bodies. It is worthy of remark, that while Herr Binz ranks the mild organic acids like the acetic, as well as the strong mineral acids among the more certain poisons to infusorial life, Dr. Richardson was able to precipitate, unimpaired in activity, his morbid pus principle from combination with acids.

It must be deemed a circumstance very favourable to the claims of Condy's fluid, that while its power in neutralizing foul and offensive products is admitted on all hands, Herr Binz has classed permanganate of potassium, its active ingredients, among the substances which have the property of acting as poisons to infusorial life.

Finally, Dr. Procter says:—"Mr. Condy diffuses his fluid through the air, mixed with the vapour of water, a plan I have not found of equal efficacy to the preceding." Diffusion in the atmosphere by means of aqueous spray, is only one of many ways of applying Condy's fluid. The vaporizer or spray-producer instrument is undoubtedly a valuable mode of bringing fluid substances rapidly in contact with the air. But it will not be denied by those who have taken the trouble to use Condy's fluid for aerial purification, according to the directions which usually accompany it, that that preparation really exerts a most remarkable purifying action on the atmosphere by exhalation of oxygen from solutions of it exposed in stationary vessels. One of the most usual methods of procuring ozone or allotropic oxygen is by acting on Condy's fluid (solution of permanganate of potassium) by sulphuric acid. It is consequently obvious that this fluid is a good available source of oxygen—"the great purifier of nature and great natural disinfectant," to use the words of Dr. Procter himself, and that by its use the wide process of natural oxidation can be imitated by artificial means. With the view of placing within reach of the public additional artificial means of disinfecting by Condy's fluid, I have been in the habit, for some considerable time, of appending the following directions:—"To act rapidly on the air, use the diluted fluid with 'Condy's Ozoniser' or other spray-producer. By the addition to the strong fluid of sulphuric acid, ozone is evolved. By that of hydrochloric acid, pure chlorine gas is disengaged."—Yours obediently,

H. B. Condy.

Battersea, London, January 3, 1868.

MEDICAL FEES IN JERSEY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—By inserting in your journal the following statement, you may perhaps rescue some unfortunate stranger from a similar fate.

In August, feeling ill, I sent for Dr. —— (residing in the town). Becoming worse, I requested a consultation, and proposed one of two medical men of high reputation here, both of whom Dr. —— declined meeting, but wished instead to have a Dr. ——. He came, and thirty-nine consultations ensued. On the 29th of September, they pronounced me recovered, and discontinued their visits. Not being satisfied with the state of my health, I consulted another medical man, and on October 13th took apartments at St. Aubin's, to be nearer him. In a fortnight I was so much better, that I returned to my house "Le Hagnais," St. Clements. Having a relapse, I again went to St. Aubin's on November 15th. On Friday, November 22nd, I was arrested at the suit of Dr. —— for £27, no bill being even then presented, or payment previously demanded, although Dr. —— had been requested to send in his account, which he declined doing until the usual time, Christmas. Being very ill and confined to bed, I was kept in ignorance of this affair. My wife offered to pay the £27, which the sheriff's officer refused to receive, unless the costs of the arrest were also paid, or perhaps, if Mrs. Collins would call and ask Dr. ——, he might forego the costs." This mode of proceeding my wife indignantly declined to adopt; and I was saved from being dragged to gaol by the decided interference of my medical attendant. The money was immediately lodged in my advocate's hands, who, on a bill of items being presented, (which I had no power of disputing) paid it the same day, disallowing costs. My baby's vaccination cost £1. 5s., Dr. —— having previously attended my wife in her confinement, and charged in proportion. On Saturday, November 23rd, next day, my effects were arrested at Le Hagnais, at the suit of Dr. ——, the consulting coadjutor, no bill having been previously furnished, or payment demanded. This arrest was immediately settled by my advocate.—Yours, &c.,

F. P. Collins.

Jersey, Nov. 27th, 1867.

A note, similar to the above, was sent by my husband to one of the Jersey papers, but was not inserted. The only difference is, that in the original letter, the names of the medical practitioners were given in full. Louisa Collins.

Sir,—I can attest the truth of Mr. Collins's statements. He had a severe attack of bilious fever and jaundice. Nov. 22, he was improving, and I felt confident of his recovery. Unfortunately, on the 24th he became acquainted with these arrests, from this shock he never rallied, and, in full possession of his intellects until nearly the last, he died Dec. 1st.

My object in addressing you is threefold—

1st. To induce the professional men of Jersey to declare their approval or disapproval of this method of coercing patients.

2nd. To caution strangers against the "perils that environ" a visit to, and a residence in, Jersey.

3rd.* To stimulate the States of Jersey (to pile Opa on Olympus were easier) to expunge from their code a law which does not exist in that of any civilised country, nor (saving Jersey) in that of any barbarous one.—Your obedient servant,

H. C. Attenburrow, F.R.C.S.

Jersey, Dec. 4, 1867.

MR. PHELAN ON THE DUBLIN LYING-IN HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I beg to trespass on you in reference to some allusions made by Dr. Sinclair to me in the "Correspondence" which he has published in your issue of the 18th December last.

Dr. Sinclair intimates that in the paper which was published in the February number of the *Dublin Quarterly Journal of Medical Science and Medicine*—1. I made an "attack on the Rotundo Lying-in Hospital"; 2. That I "brought forward the statistics of the Rotundo, to prove the baneful influence of lying-in hospitals, and *excluded* those of the Coombe in a *remarkable manner*"; and 3. "That I made it appear that the Rotundo is chargeable with increasing the immorality of the city."

* Under the law of Jersey, one person can arrest another by swearing before a magistrate that a sum above £10 is due to him. Persons holding property in Jersey are exempted from the action of this law.

I deny that I made any attack on the Rotundo Hospital. I knew that there had been for years an unusual mortality in it, and, in the cause of humanity, I published *official* documents, *that had been before published*, to show that mortality to have been the case. I supplied the paper, in question, from a deep feeling of personal duty. I expected that the publication of it would be likely to be of use, and I think it will. Witness Dr. E. Kennedy's letter.

I also deny that I excluded the statistics of the Coombe Hospital, *in a remarkable manner*, or in any manner. Every return which I gave respecting each of these hospitals was supplied by the authorities of these institutions, verified by the respective registrars; nay, these returns or data have been long known to the authorities of the hospitals, and yet none of them have complained that they are not correct. Dr. Sinclair does not point out a single error (though he has had several months to examine them) in the statistics which I have given as to the Rotundo and Coombe Hospitals.

I also deny that there is a word in my paper charging the Rotundo or its authorities "with increasing the immorality of the city," and Dr. Sinclair has not quoted any. I quoted Dr. Shekleton's evidence before the Commons' Committee to show that there was no check on the admission of unmarried women; and I also quoted an extract from the hospital charter to show that the parties intended to be relieved were "the wives of persons whose *husbands* were poor, or were the widows of such husbands, or the wives and widows of soldiers and sailors." This was not charging an increase of immorality.

I shall not notice Dr. Sinclair's personalities and puerilities. The question is, has the mortality in the Rotundo, as in other large lying-in hospitals, been occasionally much increased by the occurrence of puerperal fever; and if it has, how is that mortality most likely to be lessened? If Dr. Sinclair and his seven associates consider this question practically and coolly, they will be attended to, and will do much good; but they cannot prevent the subject from being discussed, and surely no one that reads Dr. Telford's account of the mortality in the Rotundo, in April, 1866, will say that there is not room for discussion and consideration. I know, *officially*, of the mortality that occurred during the winter and spring months of 1866 in the Rotundo, though as an official I would not publish it; but when one of the assistants gave it, I could have no hesitation in making use of Dr. Telford's letter, which shewed a greater mortality than ever I believe occurred, in a given time, in that institution.

DENIS PHELAN.

10th January, 1868.

Gleanings.

ST. ANDREWS UNIVERSITY.—From a recent return showing the number of graduates in medicine of the University of St. Andrews, from the year 1805 (inclusive) to the 1st of January, 1863, it appears that they amounted to 2510; and that their places of residence, as given at the dates at which the degrees were obtained, were as follow:—Resident in England, 1420; Scotland, 268; Ireland, 167; British Colonies, 202; places of residence not given, 453. Of those graduates of the University of St. Andrews who obtained their degrees before the 1st of January, 1863, and who are not included under clause 30 of the Representation of the People (Scotland) Bill, the number recorded as being alive in 1867 was 1342, of whom there were, resident in England, 1001; Scotland, 126; Ireland, 85; Colonies, army, and navy, 130.—*London Scotsman.*

ROBERT WATSON.—Some interesting particulars of this, in many respects, remarkable man formed the subject of a paper read before the Society of Antiquarians in Scotland. He was, it appears, born at Elgin, probably in the year of Culloden. In his early days he is said to have fought for independence in America, and on his return to Scotland to have taken the degree of M.D. He then went to London, where he was associated with Lord George Gordon, became president of the Corresponding Society, and after being tried at the Old Bailey for conspiracy, he escaped to France, and afterwards went to Rome. While here he discovered a large mass of papers, which belonged to Cardinal Yorke, regarding the rebellions of 1715 and 1745. These were subsequently sent to George IV. as a present from Pope Pius VII., and became known as the Stuart Papers. At one time he was made principal of the Scots College at Paris by the Emperor Napoleon, an office which he held for six years. In November 1838, Watson brought his singular and eventful career to an end by strangling himself in a tavern in London. At the inquest he was said to have been aged 88, but he was more probably 92; and if so, as the Bishop of Brechin remarked, "the case of a suicide at 92 is a fact unparalleled in the annals of sorrow." When at Rome, Watson became known to Professor Voghel Von Toghelstein, formerly Court painter at the Court of Saxony, now residing at Munich. This was about the year 1817, and at this time the portrait now presented to the Museum was made; but the sudden departure of Watson to Fontainbleau in search of other documents prevented its completion. He was the writer of some books. One is "Life of Lord George Gordon," another is called "An Account of an Extraordinary Disease of the Skin and its Cure," and a third was "An Answer to Work of Burke on the French Revolution." Of the first, the Bishop of Brechin writes: "It is full of fierce denunciations of kings and priests; and is an interesting specimen of that fierce and trenchant invective which was so popular among the sympathisers with the earlier stages of the French Revolution."—*London Scotsman.*

DR. LIVINGSTONE.—Hopeful news has reached us regarding the fate of Dr. Livingstone. A letter from Zanzibar, dated the 1st of October, says that an Arab ivory trader spoke of having seen the great explorer, attended by 13 followers, to the west of Lake Tanjamgika. On being shown an album of photographs, he pointed out that of Dr. Livingstone, saying, "that is the man."—*Bombay Gazette*, Dec. 14.

Medical News.

EDINBURGH UNIVERSITY.—James H. Stirling, Esq., M.D., LL.D. (Edinburgh), author of the "Secret of Hegel," and translator of "Schwegler's History of Philosophy," and author of many other critiques on philosophy, is candidate for the chair of Moral Philosophy, now vacant in the university by the lamented death of Professor Macdougall.

UNIVERSITY OF LONDON.—The following are lists of Candidates who passed the respective examinations indicated:—

B. S. EXAMINATION.

Pass Examination.—Marcus Beck, University College; William Edward Berridge, St. Bartholomew's Hospital; John Reuben Bathurst Dove, London Hospital; Henry Greenway Howse, Guy's Hospital.

EXAMINATION FOR HONOURS.

First Class.—Henry Greenway Howse, (Scholarship and Gold Medal,) Guy's Hospital; Marcus Beck (Gold Medal) University College; *John Reuben Bathurst Dove, London Hospital.

*Obtained marks qualifying for Scholarship and Gold Medal.

LIST of Entries in the Branch Medical Council (Ireland), for the month of December, 1867:—

Joseph Todd, Fairy-hill, Dromore, co. Tyrone, M.D. Univ. Edin., 1867, Lic. Fac. Phys. Surg. Glasg., 1867; George Ryan, 10, Westland-row, Dublin, Lic. R. C. Phys. Edin., 1867, Lic. R. C. Surg. Edin., 1867; James Dunne, 17, Lw. Bridge-st., Dublin, M. R. Coll. Surg. Eng., 1867, L. Apoth. Hall, Dub., 1867; William Scott Core, 29, Carlisle-street, Belfast, M.D., Qu. Univ. Irel., 1867; Edward Anderson, 68, Grafton-street, Dublin, M.D., Q. U. Irel., 1867; Lic. R. C. Surg. Irel., 1867, Lic. Apoth. Hall Dub., 1867; James William Fisher, Frankfort-avenue, Rathgar, co. Dublin, M.D.Q.U.I., 1867, M.Ch.Q.U.I., 1867; Thomas John Wilkin, Lisbellaw, co. Fermagh, Lic. R. Coll. Surg. Irel., 1867, Lic., 1867, and Lic. Midwifery, 1867, K.Q.C.Phys. Irel.; Alexander Duke, 8, Frankfort-avenue, Rathgar, co. Dublin, M.D.Q.U.Irel., 1867, Lic. R. Coll. Surg. Irel., 1867; William Albert Paxton, Parsontown, King's County, M.B.Univ. Dubl., 1867, Lic. R. Coll. Surg. Edin., 1867; Edward Joseph Curran, Ennistymon, co. Clare, Lic. R. Coll. Surg. Irel., 1867, Lic. 1867, and Lic. Midwifery, 1867, K.Q. Coll. Phys. Irel; Robert Vickers Fletcher, 6, Harrington-street, Dublin, Lic. R. Coll. Phys. Edin., 1865, Lic. R. Coll. Surg. Edin., 1855; John Harrison Nason, Newtown Lodge, Ballynoe, co. Cork, Lic. R. Coll. THE GERMS OF CHOLERA AND THE MEANS OF THEIR DESTRUCTION.

By ARTHUR ERNEST SANSOM, M.D., M.R.C.P.,

PHYSICIAN TO THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY-ROAD.

(Continued from page 45.)

We come now from negative to positive evidence. Starting with the premiss that certain diseases are caused by morbific ferments, and arguing that the influence of these ferments can be annihilated either by their own destruction, or by rendering organic matters incapable of being acted on by them, Professor Polli, in 1857, introduced an agent which he proved, by a long series of experiments, to have a real practical value. I can only record my opinion that his place, as a benefactor to science and to humanity, should be among the very highest. The agent or agents which Professor Polli introduced consisted of the sulphites and hyposulphites of the alkalis and alkaline earths.

It was found that animals could, without any apparent ill effects, swallow and absorb large doses of the sulphites. It was then observed that when the animals were killed they long resisted the putrefactive process—that whilst an animal killed under ordinary circumstances exhibited rapid and marked signs of putrefaction, an animal which had previously absorbed doses of the sulphites betrayed no sign of putrefaction whatever. Another series of experiments, and in this series three hundred dogs were the bases of the deductions, showed that the sulphites exerted a prophylactic and curative power when septic poisons were introduced into the economy.

Then, as regards the human subject. It was found that the stomach would tolerate large doses of the sulphites of soda or magnesia. They were tried in the various eruptive fevers, intermittents, typhus, typhoid, pyæmia, puerperal fever, dissection wounds, malarial infection, &c. The records of cases treated in this way show an extraordinary amount of success. Dr. Polli states—"I published my first memoir on this subject in 1861, and since that time one hundred and fifty-eight papers have been published in answer to my call; and, with the exception of five or six containing some criticisms on my labours, all the remainder confirm, in the strongest terms, by many hundreds of detailed observations, the value of these remedies."[1]

I can endorse this statement from my own personal experience. I have employed the sulphite of soda in the eruptive fevers, in malignant sore throat, in diphtheria, as well as in cholera and choleraic diarrhœa. In measles I have used it in a number of cases, always with apparent success. In scarlatina I have employed it, both internally administered and as a gargle; its efficacy in anginoid symptoms has been marked. In diphtheria I have employed it in like manner in three cases. These were all extremely severe; all but one recovered, the fatal case being a child of two years, to whom none of the sulphite was for twenty-four hours, by a mistake in the nursing, administered. In a case of small-pox the effect seemed to be wonderful. The face was completely covered with pustules, the drug not being administered till the pustular stage had arrived. There was extreme prostration, the pulse was, on November 7th, 1866, 104; the sulphite of soda, in scruple doses, was assiduously administered every four hours, and in two days the signs of danger passed, the pulse falling to 76 on November 9th. I notice that Dr. Nichol, in the *Nashville Journal of Medicine and Surgery* for August, 1866, testifies to the efficacy of the sulphites in small-pox. For cases illustrating the value of the sulphites in cholera and choleraic diarrhœa, I can refer not only to my own volume, but to the narrative of cases in my first communication to your columns. The cases there mentioned were all treated by the sulphite of soda method, and all recovered.

If it be granted that the sulphites are useful in the infecting diseases, what is their *modus operandi?* In my answer to this question I am forced to differ from Professor Polli, who says, "these salts do not act as poisons towards the several morbific ferments. . . . They do not kill the catalytic germs of the organic poisons; but they re-act on the material components of our own organism, rendering it, by their presence, incapable of being acted on by these catalytic germs."[2] The mode in which Polli supposes they affect the "fermentable stuff" of the organism is a process of deoxidation.[3] I have before said that sulphurous acid and the sulphites are not mere deoxidizers, but that they have a special influence in arresting the vitality of low organisms. Moreover, there are many arguments against Polli's hypothesis that the sulphites

act not on the ferment but on the pabulum, wherein the ferment undergoes development. In the first place what does physiological chemistry tell us of concerning the action of sulphites in the economy? Dr. de Ricci says, "Animals after having been saturated with sulphites were killed, and every portion of their body, solids and fluids, gave, on examination, unquestionable proof of the presence of the sulphites employed. These experiments seemed to prove that when sulphites, whether alkaline or earthy matters or not, are introduced into the stomach of a living animal, they may be absorbed and circulated *as such* through the organism."[1] Furthermore, "Dr. Polli found in men as in dogs, that they are not ordinarily decomposed in the stomach but pass unchanged into the blood, or, at least, appear in a brief period unchanged in the urine, and only after a while as sulphates."[2] From these facts alone it may be concluded that the deoxidizing power of the sulphites must be limited indeed, for that power could be strictly determined by their transformation into sulphates. Furthermore, if the efficacy of the sulphites depended on their deoxidizing power over the fluids of the organism, consider what an enormous quantity would be required to effect such an object! What does anology teach us? A trace of sulphurous acid or an alkaline sulphite will arrest the fermentation of a large quantity of saccharine material. The same quantity would not suffice to deoxidize the smallest fraction of this material; therefore, its efficacy must lie in some other quality than its power of deoxidation. Analogy tells us that it has a peculiar power, as I have before stated, of arresting vitality; this power is catalytic not chemical, and finds its chief exemplum in carbolic acid. There is nothing antagonistic to reason in the conclusion that substances which are perfectly harmless in the case of a high organism should be fatal to a lower organism. Common salt, among a multitude of others, presents an instance in point. I think, therefore, we cannot fail to come to the conclusion that the sulphites are readily absorbed by the higher organisms—that they circulate in the economy for the most part unchanged—that they exert a peculiar power, not upon the pabulum of the body but upon organized particles which may exist within it; and that in virtue of this septicidal power they manifest those prophylactic and curative effects which both experiment and experience have proved them to possess. We now arrive at

Proposition D.—That the germs of cholera are capable of destruction within the living body.

It may seem that this proposition admits of an easy discussion, for, according to our former conclusions, the argument might stand thus: Diseases which depend on morbid germs are to be successfully treated by sulphites or such-like antiseptics. Cholera is a disease which depends on morbid germs; therefore cholera is to be successfully treated by sulphites, &c. But this conclusion is not at this time justifiable; it can only be said that an *á priori* case has been made out.

Many circumstances may militate against the success of a treatment, though its principle may have been satisfactorily enunciated. The virus of cholera may induce such rapid effects that remedial agents of sufficient power may not be capable of withstanding it in time; or the poison may have a long period of latency, which no symptom may betray until its hold on the body has been fatally strong; or it may have a more intense power of proliferation and diffusion throughout the body than the poisons of those zymotic diseases heretofore mentioned. Or, perhaps, the sulphites which have been shown to be efficacious in other diseases, may not be powerful enough, or administrable in sufficient quantities, to kill the germs of cholera. It may be, therefore, that though antiseptics can destroy the virus of cholera outside the organism, internally administered they may be powerless. It was greatly thus in the case of cattle-plague; a mass of evidence proved the antiseptic power of carbolic acid; but the internal administration, though apparently in some cases successful, was not attended with an advantage proportionate to the value of its external employment.

Professor Polli did not claim for the sulphites the probability of a success in cholera. "Dr. Polli does not venture to assert that they will prove available in cholera or the plague; but he thinks there is reasonable ground for concluding that they will be highly useful in prophylaxis, in destroying the fermentable material on which the malignancy and fatality of these pestilences chiefly depend, and thus, render an inevitable attack mild."[1] This opinion, however, is founded on the hypothesis that the sulphites act, not upon the ferments, but upon the "fermentable material"—a hypothesis which I have considered unsound. The antiseptics act directly on he tvirus. It behoves us, as we have done in the case of other zymotic diseases, to take the evidence afforded by actual cases.

I have related in my book on cholera, cases in which the treatment by sulphite of soda was successful. All those cases related in my former communication to these columns on the Cholera Poison, were treated by the sulphites, and they seemed to show unmistakably the advantage of the mode of treatment.

Carbolic acid, internally administered, has been testified, by many observers, to have been successful in cholera during the recent epidemic. I find that so far back as December 17th, 1862,[2] Dr. Godfrey advocated the administration of carbolic acid in cases of gastric irritability, especially when produced by miasmata or sewerage exhalations; he anticipated much good from it in the treatment of cholera.

The difficulty which has been urged against the antiseptic treatment of cholera, especially by those reviewers who have noticed my book, has been that the agents administered, could not be sufficiently rapid in their action to neutralize the cholera-poison. We know, however, that the sulphites are like other salts of alkalis and alkaloids very rapidly absorbed and circulated throughout the organism—a few minutes sufficing for their diffusion throughout the economy. The argument, therefore, against the sulphites would lie not against the *rapidity*, but the *sufficiency* of their action.

On the other hand, carbolic acid is, I think, proved to be the most powerfully septicidal agent known. The difficulty in this case is its deficient absorbability. It is undoubtedly an irritant, as may be at once proved by applying a little of it to the skin—the stomach will not tolerate doses of more than two to five minims, and of this amount it is probable that only a small proportion is absorbed into the blood.

The great desideratum, in my opinion, has been an agent which should supply the qualities of the rapid diffusibility of the sulphites, with the potential efficacy of carbolic acid. This desideratum I believe now to have been supplied. Some months ago I saw, at the house of my friend Mr. Crookes, a specimen of a compound salt of sulphuric and carbolic acids with potass. I determined to pursue the method of investigation which thus opened out to me, and I have now succeeded in producing the compound salts of potass, soda, ammonia, and magnesia. I have found them to possess every quality which could be required of them, and a record of my practical experience with them I only defer to a future time.

I trust that I have now adduced sufficient evidence to show that my hypothesis of cholera-germs is not a "pure assumption," but a justifiable induction from a large mass of well-authenticated facts. I do not forget, however, that my task is even yet incomplete. I have to attempt to do, what is difficult in respect of any disease and any morbid agency—"to demonstrate each link in the physiological chain of causes by which the phenomena in question are produced." I shall not shrink from the task if space be accorded me on a future occasion.

ON A CASE OF GASTROTOMY FOR EXTRA UTERINE PREGNANCY.

By D. LLOYD ROBERTS, M.D.,
SURGEON TO ST. MARY'S HOSPITAL, MANCHESTER.

(The Substance of a Paper read at the General Session of the St. Andrews Graduates' Association.)

THE subject of the case was a woman, æt. 30, admitted into St. Mary's Hospital, Manchester. She had not menstruated for eighteen months previous to her admission into hospital. She stated that she considered herself in the family-way, as she experienced the usual feelings which attend pregnancy, and at the end of what she supposed to be the ninth month of utero-gestation she had all the symptoms of labour. She said that she had frequently felt the child. An examination of the abdomen showed it enlarged: on the right, extending upwards beyond the umbilicus and downwards towards the iliac fossa, and laterally a little beyond the mesian line, was an irregular ovoid tumour, exceedingly sensitive on pressure or manipulation. On examining the most prominent part of the tumour by palpation a decided crepitation, produced by the overlapping of the cranial bones of a fœtus, could be distinctly made out. On examination per vaginam the os uteri appeared a little higher and more to the right than normal; it was small and admitted the uterine sound to the extent of three inches, the os aud cervix uteri were normal, the uterus not so mobile. On the right side of the pelvic cavity, a hard resisting tumour could be felt. She had hectic, night sweats, vomiting, inability to take nutriments, and a small, weak, and frequent pulse. A consultation was held, it was decided to be a case of extra-uterine pregnancy, and gastrotomy was determined upon. Chloroform being administered by Mr. Runcorn, House Surgeon to the Hospital, I commenced the operation by making an incision four or five inches in length over the most prominent part of the tumour until the cyst was exposed. This being opened, a fœtus compressed, doubled upon itself, and bathed in several ounces of dark puriform, offensive matter was found to occupy its cavity. The child—a male—was at once removed. There was no vestige of the placenta. During the opening of the cyst no hæmorrhage occurred, its cavity was carefully sponged, and the external wound united by sutures and plaisters. A pad and roller completed the dressing, and the patient was put to bed. Four hours afterwards her pulse was 130, and in the evening 140; an opiate was given at bedtime, and she had some little sleep during the night. In the morning of January 21st she appeared to be sinking, and, notwithstanding the administration of diffusible stimuli and nutriments, she died about twelve A.M.

Post-mortem Examination.—The uterus was somewhat larger than a healthy multiparous organ in the unimpregnated state. The os uteri was in a perfectly healthy condition. The left fallopian tube and ovary were normal, with the exception of being bound by bands of false membrane to the back of the uterus. The fallopian tube was nearly throughout impervious. The left ovary was flattened and shrivelled. The walls of the cyst were formed exclusively by the expansion of the right fallopian tube. The parieties of this cyst varying in thickness from ¼ to ½ an inch, had contracted firm adhesions, below, to the pelvic fascia, vessels, and nerves; externally, to the caput coli, ascending and transverse colon, and to the ilium, two inches above the ilio coecal valve. At this part, the sac itself was firmly bound to the ilium. It was also *firmly* bound to the ascending colon. It occupied a transverse position in the pelvis, its length being about eight inches, its breadth seven inches. The interior of the sac was rough, not unlike that of the deciduous lining of the uterus. There existed no mark by which the site of the placenta could be ascertained. There was no communication between the cyst and the cavity of the uterus. A fine probe could be passed into the right fallopian tube for about an inch, there was no trace of the right ovary.

Remarks.—I have brought this case before the Association, not solely on account of its rarity, but because it suggested to me to collect, in a tabulated form, as far as I could, all cases of extra-uterine pregnancy wherein the operation of primary gastrotomy has been performed. This tabulation, indeed, has already, to some extent, been effected by the labours of Mr. Jonathan Hutchinson, but I have been able to increase to twice its original extent the list published by him in the *Medical Times* and *Gazette* of July 1860. These cases fully testify to the advisability of performing the operation in all conditions of the system, where the powers of life are fast sinking, and in which nature is making no effort to get rid of the fœtus either by suppuration externally or through an opening into the vagina or bowel. I have not thought it desirable to include in my table, cases of what Mr. Hutchinson very appropriately calls secondary abdominal section where ulceration has already been established, and in which the operator merely enlarges a breach previously commenced by nature. Out of the thirty-one cases tabulated, I find that fifteen terminated favourably to the mother, being nearly fifty per cent. In three cases, the children were saved. In one instance only, both mother and child survived, and this remarkable case acquires additional interest by the spontaneous expulsion of the placenta. The attempts that have been made with the view of saving both mother and child by gastrotomy have been signally unsuccessful.

Case 20 deserves a passing remark from its being one of twins. In the preceding pregnancy, delivery had been effected by the Cæsareean section, and the rupture in th uterus was discovered coincident with the line of incision which had been made during the Cæsarean operation.

In my own operation, as mentioned in the report, not a vestige of the placenta remained. I feel disposed to say, that had that not been the case, and the placenta been easily removable, I should have extracted it, thus removing an additional source of irritation. I wish also to make one remark on the question which was raised by Mr. Spencer Wells in November, 1860, in a discussion on Mr. Adams's paper on "Extra Uterine Fœtation" at the Medical and Chirurgical Society, as to the propriety of the removal of as much of the cyst as can be safely separated.

In my own case it would have been almost impossible, from its numerous and firm adhesions to the viscera, pelvic fascia, and nerves. If, however, another case were to present itself to me where the cyst was not very adherent, and the adhesions could be easily separated, I should be disposed to remove as much of it as I could without too great disturbance of neighbouring parts, for the reason already given for the detachment of the placenta—viz., because it would remove an additional source of irritation after the operation.

On the whole, a careful consideration of the recorded cases irresistibly points to the conclusion that gastrotomy may fairly rank among the legitimate operations of surgery, the proportion of successful cases being nearly fifty per cent

SURGICAL COMMENTARIES:

INTENDED AS A DIGEST OF THE AUTHOR'S PRINCIPLES AND PRACTICE, AS ILLUSTRATED BY THE MORE IMPORTANT SUBJECTS OF SURGERY.

By GEORGE MACILWAIN, F.R.C.S., Etc.

AUTHOR OF "MEDICINE AND SURGERY, ONE INDUCTIVE SCIENCE;" "THE UNITY OF THE BODY;" "DISEASES OF THE MUCOUS CANALS OF THE BODY;" "STRANGULATED HERNIA;" "LIFE OF ABERNETHY," AND OTHER WORKS.

NO. XII.—DISEASES OF JOINTS.

THERE are probably no cases presented to surgeons which are more exacting as regards the highest requisitions, both from the patient and surgeon, than the more serious disease of joints.

These requisitions, however, given, there are no diseases

which more triumphantly illustrate the extensive benefit that scientific surgery is capable of conferring on mankind.

Many of these affections are insidious in their approach, enduring in their continuance, painfully slow in their reparative processes, and though by no means always necessarily so, too frequently result in loss of limb or life. When I say by no means necessarily so, I am not supposing that the fault is always in the surgeon, or in the patient, but simply that from some circumstance or other, all the requisitions of proper treatment are either negligently or imperfectly carried out, or altogether wanting. In relation to their insidious character, some of the most serious affections commence with very little, almost no pain, unless in particular motions, or on some point of pressure, so that sometimes a disease has made considerable progress before much attention has been paid to it, and this, though it applies to patients more commonly, has sometimes lulled the vigilance of surgeons also.

Under whatever aspect they are presented to us, affections of joints should always be regarded as belonging to a class of serious diseases. In the first place, even when the result of direct injury, and therefore not necessarily connected with any constitutional disorder impeding the necessary reparative processes; still, their organization renders these reparative processes very slow, being easily impeded by small disturbances, whether constitutional or local. Again, independently of any avoidable circumstance inducing it, the constitution vividly sympathizes with injuries of these parts. There is often an amount of general disturbance which (so to speak) seems out of proportion to the local injury. Then, the occurrence of disease in these structures (independently of any direct injury) is, according to the laws regulating the sites of disease, always a *primâ facie* case, declarative of constitutional disorder; and although in many cases we see attempts to confine the diseased actions to puriform or other effusions, into the cellular tissue round the joint, yet a very little neglect soon induces deeper seated disturbance.

Diseases of joints in situations where they can be observed, seldom occur without some evidence of an attempt to determine the actions to the surface; feeble, indeed, in too many instances, and accompanied already, in bad cases, with more deeply seated complications. But whether we consider the phenomena of gout, scrofula, the various affections of joints, even those which commence in the deeper seated structures, or those cases of lumbar abscess (which, like Mr. Abernethy's first cases, occur without any disease of the vertebra), we almost always observe, *at the commencement*, an attempt to determine to the surface, and where the situation enables us to judge of it, to the cellular tissue. Even in gout, which is ultimately so destructive, it is interesting to observe how, in many cases, a naturally strong constitution, however injured by luxurious or intemperate indulgence, will strive to determine the actions of deposition to the surface of parts affected.

Diseases of joints, however, when without any external appearances, are generally not difficult of detection. If there be nothing else, there is always sufficient pain, tenderness, or uneasiness in motion (usually aggravated by bringing the surfaces of the joint in contact) sufficient to induce caution, and that generally prevents any serious mistake. It is, however, by no means a trifling error if you were to confine a patient to a sofa or bed unnecessarily, and yet there are certain obscure disorders of a limb affecting the joint, which has sometimes misled eminent surgeons. To impress this, I will relate a case which occurred to me a very few years after I commenced practice. A lady had consulted me for a trifling pain and redness on the tarsus, for which she was desired to rest and foment it. As she was of fair complexion, thin skin, and apparently of a strumous constitution, I paid attention to her general health, and in two or three weeks her foot was all right again.

About three months after this I was informed that she was again ill, and that her guardians had taken her to a very eminent surgeon, who had told them that she had a disease of her hip. I could, of course, say nothing, but that there was no evidence whatever of such disease when she was under my care. As I could not, of course, see the patient without being sent for, I communicated with the surgeon to whom she had been taken, who told me that the lady had distinctly told him that when she consulted me the disease was in her foot. "But now," said he, "if you were to see her you would see that there is disease in the hip." In a few months this lady sent for me, having become a great deal worse in health, and more pain in the limb; but on the most careful examination, I could not satisfy myself that the signs on which the surgeon had depended justified his opinion. I therefore requested her to allow me to meet him.

This she positively declined to do, but she would allow me to meet any other surgeon. I accordingly consulted Mr. Abernethy. I informed him that the question was whether there was any disease in the hip, but I did not tell him what opinions had been formed by either party. He accordingly examined the limb with great care, but with great gentleness, and then proposed to retire. I said, "No, sir, that is unnecessary. I would rather that you said at once what is your opinion." "Well, madam," said he, "I cannot discover that there is any disease in your hip." He further said that there were many cases of disturbances in the nerves of limbs, which were, he believed, dependant upon a disturbed state of the general health, and he should recommend a treatment having for its object to improve her general condition. The lady was also allowed to get up to take gentle exercise, and, with other attentions to her general health, in a few weeks had quite recovered.

It is, no doubt, very undesirable to confine a patient unnecessarily, as the health is almost certain to suffer. It is, of course, of inferior consequence compared to that of postponing unnecessarily the rest and quiet necessary to the proper treatment of incipient disease. I could relate some lamentable instances where a joint has been doing as well as could be desired, wherein the premature abandonment of the necessary measures had led to the loss of limb and life in cases where I feel certain such consequences might have been easily averted. I am bound to say that, as regards my own observation, more unnecessary amputations have been performed for diseases of joints than for almost any other disease, and I have known some of the most formidable cases brought to a favourable termination, in which the limb had been regarded as incurable by other surgeons, and by myself also.

As, therefore, it is a most painful reflection that any operation which deprives a patient of a limb should have been performed unnecessarily, no pains should be spared to carry out the necessary treatment *in all its details.*

Now, as to treatment, the thing that is, of all others, the most important, is to keep the joint in an *absolutely quiet condition*, merely resting the *limb* on a bed or chair will do nothing in serious cases. It is essential that the surfaces of the joint should be prevented from having any motion on each other. The joint should be so secured by splints, as to be essentially as one piece, so that there be no motion between the opposing surfaces.

This great improvement is one of the numerous obligations we owe to Abernethy who, very early in life, taught it in his lectures and practice. Nevertheless, many years elapsed before the practice became general or even much known. It is only, I think, in the second or third edition of Sir Benjamin Brodie's work "On Diseases of the Joints" that the application of splints is recommended.

Abernethy had at that time been teaching it for certainly nearly thirty years, and I had myself been enforcing the great importance of it after him for several years in my clinical lectures. I cannot convey more strongly the importance I attach to thus procuring absolute rest than by saying that I regard it as of more value than all other measures put together, provided only that no irregularities are permitted which are avowedly hostile to the general health.

There is, however, no occasion for this neglect. Rest should, of course, be conjoined with everything calculated to remove any disordered condition of the various organs, which, if not corrected, will be certain to retard, impede, or altogether prevent the processes of repair.

It will be necessary to materially modify the general treatment in different cases where, although the disease may differ as to its nature and the structures in which it is seated, there is the common effect of a certain absence of the usual amount of air and healthy exercise. There are patients who will sustain and even require a generous diet with moderate, and cautiously, additions of wine or beer; but, in my experience (as the rule), patients do better without *stimuli* so long as they are supplied with a sufficient quantity of wholesome and nutritious food, by which I mean meat, bread, and thoroughly well-cooked vegetables. Still, as regards general treatment, I know of no cases in which the necessity is greater for the surgeon to add to his general experience, however great, the careful observation of the *peculiarities* of the individual.

I am quite certain that diseases pathologically identical as regards the changes in the structures affected, are connected and dependant on states of constitution, which, for all practical purposes, must be regarded as different from each other in relation to the nervous system, and the primarily affected organ, however much they may agree in the common result of all disorders—viz., disturbed or deficient reparative power.

It is the saliency of this idea (I mean deficient power), I fear, which has led many surgeons to prescribe or admit the use of stimuli in cases where they have been inappropriate, and which I have often seen followed by the worst possible results. Nothing in serious cases is so *certainly* destructive as stimulants in cases to which they are *inapplicable*. If you increase action without increasing power, you are only (to borrow a simile) feeding the lamp with oxygen, as it were, and rendering the exhaustion of vital force more certain and more rapid.

I have known a case in which a patient was going on as well as could be desired, and where stimuli were admitted only in very measured quantity, in whom a change in position led to the more liberal use of stimuli (in this case champagne) under an eminent surgeon. The result was that the disease immediately progressed, and, in about twelve months, led to the amputation of the limb, the patient dying the next day.

I am desirous to impress my conviction of the necessity of a more discriminate employment of stimuli, because, I believe, it was never more necessary than at the present time; stimuli seem to be in fashion, and absurdly as such a thing sounds, there is no doubt that occasionally a habit prevails in the treatment of disease, which renders it difficult to administer remedial measures with that discrimination which is the very basis of judicious, as contrasted with routine treatment.

I have known patients call that a lowering treatment in which a surgeon has allowed a moderate quantity of good wine; and been told, that a man was put on a starving diet, who was allowed to eat mutton, beef, and poultry, with good potatoes, without any limitation but his appetite.

A wealthy patient, who was allowed a similar diet, with the addition of game, if not high, as the phrase is, but who was prohibited the use of soup, fish, and salads, said, "why sir, I might as well be in an hospital," he might have said "a great deal better." The sequel of this case was very instructive, what I have sometimes called chronic suicide. He fell a victim to his own requisitions and certain "assentations" in those under whose treatment he was, which in their judgment, of course, were admissible. The details, of the case, in many points instructive, would require too great a digression in this place. As I shall hardly have a better opportunity, I mention here an interesting case which occurred to me many years ago, as it conveys a practical caution:—A young lady had an attack of fever in the country, and when she removed from that, it was found that she has very little, indeed, almost no power of motion in her left leg; on this, she was brought to town for my opinion on the case. The opinion I gave was essentially, that I regarded the case as one of the sequelæ of fever, which was not very uncommon, at all events in a large public practice. I had seen, I thought, several cases in the course of years of the same character; that as to prognosis, I had very little apprehension; that I expected that as she gained strength, she would in time, by attention to her general health, good air, and so on, recover the use of the limb; very eminent practitioners, the one a surgeon, the other a physician, differed materially from this view. They regarded the case as belonging to the class of paralytic affections, and considered the proper treatment would involve a mild course of mercury. As this was, in every point of view, an opinion in which I could not coincide, and as the somewhat strumous aspect of the patient induced me to think her a most unfavourable subject for mercury, I retired from the case; at this time, there was no difference in the limbs whatever. I heard no more of this case, for, I think, nearly two years, when I received a letter from Paris, from the father, written in a very anxious and despairing tone, saying that he would be in London on a certain day, and, with some complimentary mention of my former opinion, that he wished very much to consult me; that two of the most eminent surgeons in Paris had said that the hip was dislocated. As I did not happen to be in London at the moment of his arrival, he consulted two of the most eminent surgeons in London, both of whom concurred as to the dislocation of the hip. The only exception being (if I may call it so) that one of them, the late Sir Wm. Lawrence, said that he certainly had never seen such a case before, but still his impression was that the hip was dislocated. I could not, of course, say what might, or might not, have happened in so long an interval, especially after the treatment to which I had objected. When the patient arrived, I examined the limb very carefully, and then I examined the spine; here, as it appeared to me, lay the true explanation of the case. It did not appear that any of the surgeons had examined the spine, which to me satisfactorily accounted for their not detecting the real nature of the case. The lady had been allowed to walk with crutches, and this had led to a curvature of the spine. When placed in a position fairly to test that point, the limbs were of the same length. The parts, in relation with the hip, were in their right position, and the case became perfectly clear. As, however, I had been formerly a good deal annoyed about the case, I insisted that the father should take another opinion, and in the meantime I showed him on the skeleton what had happened. Well, he chose Sir Astley Cooper, who was still in practice. I ventured to preface his examination by saying—"Now, Sir Astley, you are to say what is the matter with that hip, because, if my opinion is right, the case has been mistaken by four very eminent surgeons in Paris and London. I do not say, sir, that it will deceive you, but I am sure it may, unless you examine it attentively." I gave Sir Astley no hint as to what any of the opinions were. Sir Astley proceeded to examine the limb; having done so very thoroughly, he proceeded to examine the spine, when he said he saw the nature of the case, adding, "there is no fracture, dislocation, or disease in the hip;" the appearances result from a curvature of the spine. He then took a piece of chalk and proceeded to sketch the position of the parts in the same manner as I had showed the father the previous day in the skeleton. I felt certain that there could be no difference between surgeons who would take time to examine all the points of the case, and that was the reason of my desiring that Sir Astley should be particular. On telling him the origin of the affair when I had formerly seen her, I assured Sir Astley that it was, in my experience, no uncommon sequela of fever, and that in time and proper treatment, the limbs, if properly treated, recovered their power. "Why," said Sir Astley, "when I was in the city, I should say a year seldom passed without my seeing three or four cases of the kind."

Few men were more quick in detecting the nature of

this sort of case than Sir Astley, but he was wont to be very quick, and not being averse from something like display he would sometimes, amidst numerous brilliant successes, overlook what a mere quiet examination would detect. In the case of alleged hip-disease, mentioned in this commentary, I have no doubt, from what I heard of the examination, that haste was the source of error. The lady told me that the surgeon took hold of the limb and twisted the thigh outwards, and when she complained of pain he immediately decided that there was disease of the hip. Now, to say nothing of numberless cases in which fugitive pains in joints do not involve what we understand by disease, the very movement she described would, I conceive, put the ligamentum Teres of the hip somewhat on the stretch, and occasion the pain in question. To return to diseases of joints, I used at one time to attach a good deal of importance (in prognosis) to the structures in which the disease might be supposed to have commenced; and again to those which might be involved at the time the case was first presented for observation. Further experience has convinced me that I greatly over-rated the importance. I do not mean that they are not important in relation to anchylosis, but that my prognosis, as regards the *ultimate* safety of the limb, is much less governed by such circumstances than formerly. Few points in the treatment of diseases of joints require more discrimination than the use of counter-irritants. I know not any terms in which I can briefly express a rule for the use or the omission of this class of remedies.

With a fair amount of power I think they are very useful, but where the evidences are the other way, the pulse feeble or too frequent, appetite below par, or somewhat deficient, and the nervous system excitable, they are of doubtful propriety; nevertheless, I have seen them very useful, where, in the cautious trial of them, I had been distrustful of them. Small blisters allowed to heal, and then repeated on the neighbourhood of the joint, are good modes of testing their applicability. I have not seen them of themselves do much good, but they are convenient as *avant coureurs* of more efficient measures, as issues. Both issues and setons are, in my experience, often made too large, the less pain or inconvenience that the patient feels from them the better. All that plan of dressing them with irritating irritants I regard as unnecessary or injurious.

There has been, I think, a tendency in those who employ counter irritants to regard them as chiefly useful in cases where the bones are affected; my experience does not enable me to confirm any such exclusive reliance on them, but they require attention to many circumstances which I have often observed to be disregarded. They are applied too indiscriminately, or rendered unnecessarily painful. I have formerly seen issues made so large as to constitute, in the state of the parent's health, a serious local injury, and, again, setons not only too large and long but made to discharge by irritating ointments, &c., as I have already said, all this is, in my idea, a mistake. In my view, a counter irritant is an attempt to assist the economy in determining to the surface actions that are destroying more important structures, but the setons or issues, &c., do not, *per se, give the power*, hence the propriety of their application depends on a discriminate view of the condition of the patient. Issues should at first be small, one that will enable you to insert three or four small glass beads (never peas) is quite big enough. Setons should be made with a small needle, the one I use at first is scarcely more than half the size of the ordinary instrument. In all cases friction to the skin *generally* is almost certainly beneficial. Friction *over the joint*, though a powerful remedy, depends on the time and circumstances under which it is applied. It is seldom safe before the joint has been brought to a state of comparative quiescence. The well-known successes which attended the practice of Mr. Grosvenor, of Oxford, and of Mr. Scott, formerly of Bromley, seem to have been dependant on this determination to the surface in the former case, and in the latter to the comparative quiescence which his plaisters tended to ensure, as also to the exhalation from the skin which their composition promoted. The mischief which has sometimes occurred from friction and counter irritation in diseases of joints, has resulted from the successful application of them having usually been extensively reported, *whilst the failures have not been reported with equal fidelity.* This has led to a too indiscriminate employment of these measures, notwithstanding that cases have occurred warning us against such indiscriminate practices. Amongst all diseases of joints hardly any are more serious than scrofula, yet if the internal organs are sound, and the necessary time and care given, they will, most of them, ultimately do well.

We can, indeed, hardly walk our streets without witnessing numerous examples of shortened and otherwise crippled limbs, the result of scrofulous disease; yet these cases, deplorable as they are, are still proofs that after a time the diseased actions have ceased. There is no doubt that many of these mutilated conditions might have been prevented had the patients been placed in circumstances at an early period affording a sufficiently enduring rest and other proper treatment. Whilst, however, under the actual circumstances of the patient, amputation may have become necessary, it is probable that very many amputations of joints which were unnecessary have been cases of scrofulous disease. I was one day going round St. George's Hospital with Sir Benjamin Brodie, many years since, when, looking at some cases of diseased joints, I observed, "we say" (alluding to the school of Abernethy), "that all these diseases will do well with sufficient rest and proper treatment." Sir Benjamin assenting, replied, "I have never amputated, in private practice, more than thirteen times in my life." No doubt persons in easy or affluent circumstances can give whatever time may be required, together with good air, certain kinds of exercise by gestation, and such means as are not to be found in hospitals or large and crowded cities. Indeed, Abernethy himself was wont to say of these as of other curable forms of serious diseases, "but do you think you can accomplish this in the air of an hospital?" Even in private practice people naturally become impatient, that renders them often intractable, then they are wavering in their confidence, and thus, under the influence of powerful but still secondary causes, throw away the advantages of their position until the vital forces become exhausted by continued contest, whence they can only be relieved by rendering further attempts at repair unnecessary or restricting it to the healing of a wound made by amputation.

Hospital Reports.

ST. THOMAS'S HOSPITAL.

CARIES OF TIBIA—OPERATION—DISEASE ENCROACHING UPON KNEE-JOINT—AMPUTATION OF THIGH—NECROSIS OF HUMERUS—RECOVERY.

Under the care of Mr. SIMON.

AMELIA G., æt. 7, a poor, emaciated, forsaken child, was taken into Queen's Ward, under the care of Mr. Simon, Aug. 31, 1866, with abscess in the right shoulder.

She had been half-starved and badly clothed for some time, and the shoulder had been bad apparently for a month or so, but not actively affected until a few days before admission, when she had fallen and hurt it. The history was unsatisfactory; no friends ever visiting the child or giving any account of her illness to the sister of the ward.

There was a large abscess over the pectoralis major on the right side, extending to the inner and upper part of the arm, over the biceps and brachial vessels. The superficial veins were greatly enlarged. This abscess was incised, and a large quantity of thick pus evacuated.

On September 8th, it was noticed that the right knee was painful and swollen, and tender on pressure over the

outer side. This was placed on a splint, and a blister applied, but the knee became worse, and abscesses formed, first on the outer and afterwards on the inner side, and were laid open.

The arm wound healed, and the knee became a cause of serious alarm for the safety of the child. On December 7th, a sinus remained on the outer side of the head of the tibia, and a probe could be passed through the head of the bone into a carious cavity beyond. This was laid open by Mr. Simon, when the child had been placed under the influence of chloroform. The wound in the skin was gradually enlarged during the operation, until it was made nearly three inches long, and the gouge was carried in the direction of the sinus, but along the lower part of it, so as to make a way into the carious cavity beyond. Here a good deal of carious detritus was found and cleared out, and free vent was left. In this operation nearly the whole of the lower half of the epiphysis was removed, the cavity cleared out, no sequestrum found, but the upper end of the shaft of the tibia seen to be carious, and therefore gouged away. The knee-joint did not appear to be materially affected if at all so.

On December 29th, or twenty-two days after the operation just described, she had sunk again after the short rally which followed the removal of so evident a source of irritation. She was now extremely exhausted, and reduced to a mere skeleton, the knee wounds were discharging copiously, and suppuration had extended up the thigh. Mr. Simon, therefore, thought it necessary to amputate immediately in order to give the child any chance of recovery. He amputated the thigh between the middle and lower thirds, by the circular method, using skin as almost the sole covering for the bone. The parts were very bloodless, and the femoral was the only artery tied. There was some bleeding from the vein, and this vessel was obliged to be ligatured, but it was freed from the ligature afterwards.

On the examination of the bones removed, we extract the following report from the Registrar's notes:—"Epiphysis now pretty extensively united to shaft. The deep, gouged channel much reduced by recent bone-formation; finger can be passed into knee-joint through the dissolved and ulcerated cartilage on the outer head of tibia; ulceration also on the opposed surfaces of femur, and tibia on inner side of joint; suppuration in popliteal space connected with disease of bone behind head of tibia."

She improved with wonderful rapidity after the operation. The stump healed readily; the ligature came away on the ninth day; she gained strength, and, from being a mere living skeleton, apparently beyond human aid, she became a cheerful, well-nourished, and healthy-looking child.

On March 6th, a sequestrum was removed from the humerus, about four inches in length, and involving about half the thickness of the shaft; but this does not appear to have given rise to much pain or inconvenience—the sinuses over the sequestrum, in fact, did not form until a few days before its removal, nor did it interfere with her general health. She continued to improve, and remained in hospital until all the sinuses were healed and a wooden leg could be adapted, and was discharged cured, August 21, 1867, 355 days after admission, and 235 after amputation. The last two months of her stay were more out of charity than from the surgical necessities of the case.

Remarks.—Taking into consideration, first, the disease of the knee-joint, it seems that in this case the primary mischief was caries at the line of junction of the upper epiphysis of the tibia with the shaft, and, in this respect, differs from the causes of joint disease, exemplified in the two cases of joint disease reported from this hospital in the MEDICAL PRESS AND CIRCULAR of December 4th. The main affection was on the outer side. It was here that the first abscess formed, and it was at this position that perforation took place into the joint, as was seen by the examination of the bones after amputation.

From the outer side, or nearly simultaneously with the primary disease, caries extended through the epiphysis, and a cavity formed in the back of the bone, and this was cleared away to a very great extent by the first operation. The disease advanced, however, through the outer articular surface of the tibia, and it would appear that a large spot of caries remained in the posterior surface of the bone, and this gave rise to the subsequent suppuration in the popliteal space.

That the first operation was most effectual is evident from the healthy condition of the parts which had been gouged; and it was owing to the exhaustive condition of the patient, together with the extension of disease into the knee-joint, that amputation of the thigh was made necessary.

In regard to the operations, the gouging was very extensive, and as far as could be felt, no trace of disease was left in the parts exposed. The caries was peculiar in not being confined to the epiphysis, but affecting also the upper end of the shaft; and this would not be expected in a child in whom the epiphysis were completely distinct from the shaft. All disease being apparently cleared away, free exit was made for the discharge—a point which Mr. Simon is most careful to insist upon. It is a great and instructive pleasure to watch the operations on bone performed by this surgeon, and to learn, by example, how to apply science and common sense in surgical operations no less than in other methods of treatment. Operations on bone usually fail from incompleteness, and the magnitude into which an apparently trivial operation on these tissues grows while on the operating table, is often enough to deter an ordinary surgeon from satisfactorily completing it. We speak from authority, when we say, that a very large number of the cases of bone disease admitted into Margate Infirmary, where the experience of this form of disease is almost the largest in the kingdom, have been under treatment in other hospitals, and, in many instances, discharged as cured, and that only a short time before their admission at Margate. Doubtless, in many of the cases, time has been the means of allowing a more perfect separation of sequestra, and parts which appeared previously healthy, or at most doubtful, may have become pronounced in disease; but many may be traced to insufficient and ineffectual operations.

Another feature of interest here, was the rapid convalescence after total removal of the disease; and the other point worth remarking, is the existence of the sequestrum in the humerus; but whether this was the cause of, or secondary to, the abscess in the shoulder on first admission, the history of the case does not clearly prove.

KING'S COLLEGE HOSPITAL.

Cases under the care of Dr. BEALE, F.R.S.

(From brief Notes by Dr. TONGE.)

TYPHOID FEVER.—Elizabeth W., æt. 17, servant. Admitted May 20, discharged June 11; in hospital 22 days. *Recovery.* Previously ill, 14 days. Began with shivering on 16th day; pulse 96; respiration 24; slight delirium; tongue furred at edges; 8 or 10 rose spots over chest and abdomen, the latter rather tender; wheezing over lungs; purging slight, none after 19th day. No fresh spots after 21st day; free from delirium on 26th day; well on 33rd day.

Aromatic spts. of ammonia; liq. ammon. acetatis and chloric ether. Brandy, 2 oz.

TYPHOID FEVER.—W. E., æt. 23, labourer. Admitted March 7, discharged March 26; in hospital 19 days. *Recovery.* Access gradual. Previously ill, 6 days. On 7th day much headache; sleeplessness; tongue furred, red at tip; several rose spots on tumid and tender abdomen; pulse 92, respiration 36; rhonchus over back of chest; purged once on 7th and once on 13th day. No fresh spots after 15th day; no delirium. Well on 23rd day.

Bark and dilute nitro-muriatic acid (2 days). Chloric ether, aromatic spts. of ammonia and liq. ammon. acetatis (10 days). Then dilute muriatic acid and bark. Brandy, 6 oz.

Typhus.—M. L., æt. 43, needlewoman. Admitted June 23, discharged August 6 ; in hospital 44 days. *Recovery.* Previously ill, 6 days. Anorexia ; thirst ; loss of strength ; drowsiness ; inflammation of right parotid. On 7th day, pulse 100, feeble ; marked rubeoloid rash, delirium ; deaf on right side. An abscess formed in right parotid, and opened into the external auditory meatus on 14th day. Convalescent on 41st day.

Aromatic spts. of ammonia, liq. ammoniæ acetatis and chloric ether (7 days). Then quinine and sulphuric acid. Brandy, 9 oz. Abscess opened.

Typhus.—Maria C., æt. 35, married. Admitted June 17, discharged July 23 ; in hospital 36 days. *Recovery.* Previously ill, 6 days. No shivering, but heat of skin ; vomiting ; anorexia ; headache ; sleeplessness. On 10th day, pulse 120 ; tongue slightly furred ; wheezing over back of lungs ; faint measly rash on trunk ; purged slightly throughout. Convalescent on 29th day.

Aromatic spts. of ammonia, chloric ether and liq. ammoniæ acetatis. Afterwards quinine and dilute hydrochloric acid. Pepsine. Brandy, 6 oz.

Typhus.—S. B., æt. 25, labourer. Admitted May 10, discharged May 25 ; in hospital 15 days. *Recovery.* Out of work and ill fed 5 months. Previously ill, 17 days. Laid up 2 days ago. On admission (18th day) face dusky ; headache ; lassitude ; thirst ; dry dark brown tongue ; fading rubeoloid rash on trunk ; pulse 72. On 25th day, pulse 54 ; eruption gone. Convalescent on 28th day.

Dilute nitro-muriatic acid chloric ether and liquor cinchonæ (2 days) ; liquor ammoniæ acetatis and aromatic spts. of ammonia (5 days) ; then quinine and dilute sulphuric acid. Brandy, 6 oz.

Typhus.—Emily P., æt. 26, married. Admitted Sept. 23, discharged October 22 ; in hospital 29 days. *Recovery.* Previously ill, 1 week. Shivering ; pain in limbs ; weakness ; loss of appetite ; constipation ; headache ; sleeplessness. On 9th day, crepitation at base of lungs ; pulse 120 ; respiration 28. Distinct and abundant rubeoloid rash on 10th day.

Liquor ammoniæ acetatis, aromatic spts. of ammonia and chloric ether (6 days) ; tinct. opii and decoction of bark (1 day) ; then aromatic spts. of ammonia and bark ; starch and opium enema on 13th day.

Typhus.—C. S., æt. 10. Admitted September 26, discharged October 22 ; in hospital 26 days. *Recovery.* Previously ill, 5 days. On 6th day, skin hot, dry, and pungent ; abdomen and arms mottled ; tongue brown in centre ; red at tips and edges ; pulse 120 ; respiration 44 ; very drowsy. On 9th day, pulse 132 ; respiration 32 ; purged thrice. On 10th day, pulse 100 ; purged 5 times. On 13th day, pulse 104 ; purged 3 times. Convalescent on 17th day.

Carbonate of ammonia chloric ether and liquor ammoniæ acetatis ; same with decoction of logwood ; afterwards dilute nitro-muriatic acid and liquor cinchonæ. Brandy, 4 oz.

Typhus.—H. F., æt. 24 ; nurse in K.C.H. Admitted January 3, discharged February 24 ; in hospital 52 days. *Recovery.* Previously ill, 3 days ; no distinct rigor. On 4th day, severe headache ; nausea ; brown tongue ; pulse 130 ; rubeoloid rash on 5th day ; slight delirium on 6th day ; afterwards much restlessness. On 14th day, very prostrate ; sordes on lips and teeth ; tongue brown and dry ; pulse 140 ; intermittent and feeble. Began to improve after 16th day ; purged not more than 4 times daily till 23rd day. Convalescent on 24th day ; Well on 42nd day.

Liquor ammon. acetatis, aromatic spts. of ammonia and chloric ether (9 days) ; aromatic spts. of ammonia (12 days) ; then dilute muriatic acid, chloric ether and liquor cinchonæ. Brandy, up to 24 oz. ; enemata of beef-tea, quinine and brandy ; astringents for diarrhœa.

Typhus.—C. H., æt. 25, costermonger. Admitted December 28, 1863, discharged January 25, 1864 ; in hospital 28 days. *Recovery.* Previously ill, 14 days. On admission (15th day) rather deaf ; headache ; tongue yellowish brown, dry and tremulous ; no appetite ; pulse 120 ; respiration 30. Faint rubeoloid rash on trunk, with a few petechiæ. Trace of albumen in urine (4 days). On 17th day rhonchus and sibilus over lungs ; coarse crepitation at bases ; frothy expectoration ; pleuritic rub at lower part of left side on 23rd day ; nocturnal delirium till 22nd day. Convalescent on 29th day.

Quinine dilute muriatic acid chlorate and nitrate of potass and sp. eth. nitric (2 days) ; same with tinct. scillæ (5 days) ; arom. spts. ammonia chloric ether and tinct. scillæ (2 days) ; same with liq. ammon. acetatis (2 days) ; then quinine and dilute muriatic acid. Brandy, 12 oz. ; turpentine stupes.

Typhus.—G. C., æt. 18, printer. Admitted September 18. *Died* on September 28. In hospital 10 days. Caught from family. Previously ill, 2 days. Pain in back, constipation and thirst ; rash appeared on 5th day ; distinctly rubeoloid on 6th day ; urine 1-6th albumen ; on 7th day tongue brown, glazed, and tremulous ; expectoration, viscid mucus streaked with blood ; purged twice yesterday ; on 9th day many petechiæ on abdomen ; much subsultus ; pulse 148 ; respiration 32 ; on 10th day violently delirious, refusing food ; on 12th day unconscious ; pulse 172 ; respiration 48 ; died on 13th day. *Post-mortem.*—Lungs emphysematous ; slight renal congestion ; liver somewhat soft.

Aromatic spts. of ammonia chloric ether and liq. ammon. acetatis. Brandy to 18 oz. Liq. morph. acetatis ℥xx. on night of 24th. Emp. Lytt. to forehead and behind ears.

Typhus.—Mary A. N., æt. 13, servant. Admitted May 6. *Died* May 14. In hospital 8 days. Previously ill, 5 days. Headache ; shivering ; loss of appetite ; slight sore throat ; on 7th day, pulse 120 ; face dusky ; eyes suffused ; slight delirium ; distinct rubeoloid rash all over her. Tongue, brown and dry ; skin hot and unperspiring throughout ; the delirium continued ; on 12th day began to pass motions and urine under her ; gradually became weaker ; died comatose on 14th day. *Post-mortem.*—Slight congestion of lower pulmonary lobes ; spleen and liver rather soft.

Liquor ammon. acetatis and aromatic spts. of ammonia, pepsine ; enemata of beef-tea, brandy, pepsine, and quinine. Brandy up to 12 oz.

Typhus.—Timothy D., æt. 10. Admitted June 7. *Died* June 9. In hospital 2 days. Previously ill, 10 days. No marked shivering ; headache ; pains in limbs ; sleeplessness ; thirst ; loss of appetite ; diarrhœa ; petechial eruption on 5th day ; on 11th day eyes suffused ; face dusky ; cannot be roused to answer questions ; abdomen tender and tympanitic ; numerous petechiæ on trunk and limbs ; tongue dry and blackish brown ; sordes on teeth ; pulse 120 ; respiration 44 ; sibilus in front of lungs ; crepitus at bases behind ; death on 13th day. No *post-mortem.*

Turpentine ℥x. 6tis horis. Brandy to 9 oz. Pepsine. On 13th day, liquor ammoniæ acetatis and chloric ether.

Typhus.—Ellen K., æt. 23. Admitted August 29. *Died* on September 3. In hospital 5 days.

Dilute muriatic acid, chlorate of potass and bark ; pepsine ; brandy 24 oz.

The Management of Lunatics.—An inquest just held at the Abergavenny Joint Lunatic Asylum shows how little restraint is sometimes exercised over really dangerous lunatics. One of the inmates of the Asylum, a Mrs. Mullard, was found strangled in bed. It was stated in evidence that the apron found on the neck of the victim was that of another patient, who said that hearing Mrs. Mullard "praying to God" she thought "she would send her to him at once." Notwithstanding this important circumstance, the jury, with proverbial intelligence, returned a verdict that "the deceased died from suffocation, but how caused there was no evidence to show."

Professor Faraday's Library will be sold early next month by Messrs. Puttick and Simpson, at their rooms in Leicester-square.

Foreign Medical Literature.

REPORT OF AN OPERATION FOR HERNIA CEREBRI: WITH OBSERVATIONS.

BY DR. MED. H. HIRSCHSPRUNG.

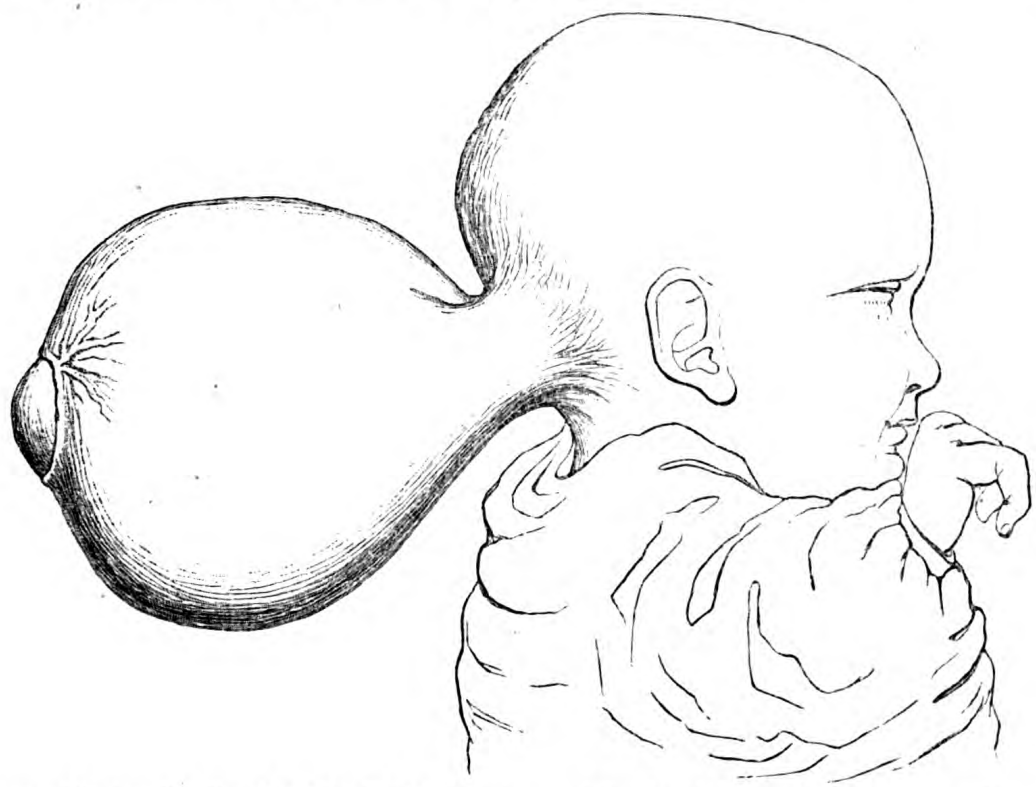
Translated, with abridgment, from the *Ugeskrift for Læger*, Nos. 16-19, March and April, 1867.

By W. D. MOORE, M.D.Dub. et Cantab., M.R.I.A., L.K.Q.C.P.I.

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS; OF THE NORWEGIAN MEDICAL SOCIETY; AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; SECRETARY FOR SWEDEN, NORWAY AND DENMARK, TO THE EPIDEMIOLOGICAL SOCIETY OF LONDON.

On Saturday, the 10th of February, 1866, I was called out by a midwife to see a newly-born female child, in the city, who had come into the world with a large tumour in the occipital region. The mother was a recently-married primipara, of strong appearance, and neither in her family nor in that of her equally healthy husband (they were both from Flensborg) had any, so far as was known, malformations occurred. To my question whether anything remarkable had happened to the mother which she could connect with the condition of the child, she stated that during the early months of pregnancy, while she was living with a tavern-keeper in Tivoli, and had to bring water from the moat, she had fallen in, and was helped out only on giving the alarm—an accident which had, of course, affected her very much, but had otherwise left no apparent consequences. Her pregnancy had run a perfectly normal course, except that the birth of the child had taken place about a fortnight before it was expected; thus she had menstruated last on the 7th May, and thought she became pregnant on the 14th, or one of the immediately subsequent days. Her labour commenced in the afternoon of the 10th February. On the arrival of the midwife the os uteri was already much dilated; shortly after the waters came away; nothing remarkable was observed on repeated exploration, which showed that the head was presenting. After the labour had continued altogether scarcely two hours, the child was born, and it was not until after it was expelled that an enormous tumour was discovered on the back of the head, which, it was supposed, had lain, during the passage through the pelvis, on the child's neck. Shortly after the placenta came away, and on examination presented nothing morbid. It was small; the funis was thick, fat, with bulgings out in a couple of places. I may here add that convalescence proceeded quite normally, and that the mother the very day after her confinement had plenty of milk, so that the child could be applied to the breast.

The child was small, and seemed still to want about a fortnight of perfect maturity. It was, with the exception of the tumour proceeding from the occipital, perfectly formed, cried lustily, and took eagerly the *eau sucrée* given to it, and soon after birth passed meconium. Our whole attention was therefore concentrated on the tumour. This arose by a short, thick stem from somewhat below the middle of the occipital bone, and subsequently expanded into an oblong, purse-shaped swelling, which was quite flaccid, and assumed different directions and shapes, according to the position of the child. It was evident that it contained a thin fluid, and examination with a candle showed also that the tumour was transparent. As is seen from the drawing (made by Dr. Lütken), it is placed on the same plane as the head of the child, which rests on the left side. Measured in this position, it gave the following magnitudes: from side to side, 4½ inches; from above downwards, 4 inches; height from the table, 2 inches; circumference of the tumour at the broadest part, 10 inches; circumference of the stem, 3½ inches.



The sac was a direct continuation of the skin of the head, the colour and other appearances of which it retained, except that the skin became a little thinner the farther it was removed from the head. It was provided with a fine network of capillary vessels, which filled when the child cried, reddening the colour and increasing the warmth of the part, and on the stem and a short way along the tumour was a growth of fine hair. On the end farthest from the head were whitish, firm cicatricial striæ radiating in various directions. Directly beneath this part, quite posteriorly, the skin was highly attenuated, or more correctly, was quite deficient, and replaced by a thin, transparent membrane, which projected as a protuberance, and, when more fully distended, seemed to threaten to burst. Similar, but very small spots, were seen in a couple of places between the cicatricial striæ. On pressing in towards the skull at the starting point of the tumour we distinctly felt proceeding from the bone and projecting into the neck of the sac a smaller, as it seemed, very solid tumour, with a broader base, situated about in the middle line, but yet with its greater half to the right side. As it extended about an inch into the sac, it was felt at one part in close connection with the inside of the latter, but terminated thereupon thinner and irregularly patched. It lay with its base immovable upon the bone, and could not be pressed back. Neither was it possible to demonstrate the ex-

istence of any opening in the bone ; only by passing the finger from above down towards the seat of attachment of the small tumour did one get the sensation of sinking into a slight depression. I may add that the attempt to compress the sac did not produce any diminution of its circumference, and consequently no symptoms of pressure on the brain. The shape of the head presented no peculiarity, the fontanelles and sutures were tolerably large, but not more so than might be expected in consequence of the child's somewhat premature birth. The measurement around the forehead and occiput was twelve inches, and must therefore also be considered normal.

At a subsequent point of this communication I shall speak of the diagnosis more at length ; but I may be permitted now briefly to mention the considerations which directly presented themselves, and influenced the treatment. There could be no doubt that we had to deal with a tumour, which in one way or another was connected with the organs in the cranial cavity. In favour of this view were decidedly our experience of the usual nature of such tumours, its situation, its watery contents, and the solid production proceeding from the cranium itself, and projecting into the sac. Vastly more difficult it seemed, on the contrary, to decide whether the smaller tumour consisted of a process of the cerebral membranes, which in view of the considerable and almost cartilaginous solidity recognisable by the touch, could not be looked upon as quite inadmissible, notwithstanding the great rarity of such a case, or whether we had to deal with a hernia of the brain itself, against which assumption the consistence of the tumour seemed to testify, while its situation in one of the favourite localities of cerebral hernia and the comparatively frequent occurrence of the latter were well adapted to excite a justified suspicion. Further, it was necessary to inquire, a point which might be of great importance with respect to the question of eventual operation, whether a hope might be entertained that the direct communication with the cavity of the skull, which, at all events, at an earlier period had existed, might now possibly be interrupted by the closing of the intervening opening. It was not possible to feel any opening in the bone, and pressure on the tumour did not diminish its fluid or solid contents.

These several questions I canvassed in conjunction with Professor Brünniche and Dr. Studsgaard, without our being able to come to any definite conclusion. With respect to two things we were, however, agreed—namely, the duty of endeavouring, by artificial means, to remove a malformation which, even if it were compatible with life, must make the latter a burden; and, secondly, the necessity of not deferring the attempt too long, if we would not consign the child to certain destruction, as the tumour might any moment give way, whereby, in all probability, such a violent suppuration would be produced in the large sac as to carry off the child, not to speak of the probability of unfavourable complications. We determined, therefore, to remove the tumour, and to do so as soon as possible, and it now remained only to decide on the mode of operation. The child's tender age would necessarily require the gentlest proceeding, its feeble strength would demand a method unaccompanied with loss of blood, and which would not in the process of healing draw too largely on the system; the stalked form of the tumour suggested the use of a ligature, while, nevertheless, its comparatively thick neck, with its more solid contents, made it doubtful whether a silk, or even a metallic, thread would be able to penetrate it ; in a word, all interests seemed to combine to demand the employment of Chassaignac's écraseur, and we finally decided in favour of this instrument.

On Monday, the 12th February, at one o'clock, we proceeded to operate. The child had, therefore, at the time not completed 48 hours. During the operation, which was performed by Dr. Studsgaard, and which lasted about 20 minutes, the little patient was kept under the influence of chloroform. It gave no apparent sign of pain, and awoke immediately after the cessation of the operation. The sac was first evacuated by puncture. It contained about 12 ounces of a highly blood-coloured, clear, and but slightly viscid fluid, which, after removal, became somewhat thicker. The chain was then brought around the neck of the sac, and, with slow movement of the instrument, ceasing about a minute between each tightening of the chain, the tumour was cut off with great ease. Immediately after, however, the skin became strongly retracted on all sides, and exhibited throughout a circuit of one and a half inches in diameter, a wound covered with the subcutaneous connective tissue, in the middle of which was observed a circular, dark-red spot of about three lines in diameter. This represented the truncated stem of the inner tumour projecting through a corresponding opening in the bone, directly over the spina occipitalis, which was situated unusually low down. By the side of the dark part a fine probe could be passed an inch into the cavity of the skull without meeting any resistance. Deeper probing was considered unadvisable. After a slight hæmorrhage from the connective tissue had been arrested, the wound was united by three sutures, then covered with lint and a bandage (Funda).

Lector Reisz was so good as to give me the following more accurate description of the sac and its contents :—

The fluid was highly sanguineous, and on standing deposited a coagulum at the bottom of the glass. Under the microscope numerous blood corpuscles with epithelial scales were seen. It was not chemically examined. The wall of the cyst was formed of the skin, and the subcutaneous, rather scanty connective tissue ; within this followed a layer of fibrous tissue forming the innermost lamina of the wall of the cyst. On the most prominent part of the cyst was seen a somewhat retiform structure, consisting of thick decussating fasciculi of connective tissue. Down towards the neck of the cyst the fibrous membrane becomes thicker, and is divisible into two, in some places even into three laminæ (pericranium + dura mater—pericranium + two layers of dura mater). In this fibrous membrane run tolerably large vessels, veins and arteries, lying close to the inside of the membrane ; where this divides into two laminæ the large vessels run in the innermost. The tap, which projects as a pyriform tumour, 5-4ths of an inch in length and 3-4ths of an inch in breadth, is invested with a loose connective tissue, in which are seen numerous vessels and small ecchymoses (pia). It is of somewhat softer consistence than the normal cerebral mass, and is continued into a round stem one centimètre in length by about four millemètres in thickness, which is somewhat firmer than the tap itself. On section, this is found to consist of two differently coloured substances : an external peripheral layer of a dark grey colour, with numerous bloody points and blood-red streaks, and striæ of two or three millemètres in thickness, and a central layer lying within this which occupies the greater part of the tumour, and is of a deep red colour, occurring partly in points, partly as radiating, red striæ proceeding from the stem. Between the compactly placed points and striæ the mass presents a whitish colour. In the stem itself the two substances are not to be distinguished from each other, the colour being there uniformly blood-red. On microscopical examination the grey peripheral mass is seen to contain innumerable blood-corpuscles, in part scattered without arrangement, in part evidently enclosed in minute vessels. The principal mass is composed of a finely granular intercellular substance entirely resembling that of the cerebral tissue, in which are scattered nuclei, which, in the most superficial part of the peripheral layer are fewer, but become more numerous more internally. The nuclei are of various shapes, varying on section from 0·002 to 0·005 mm. in diameter. In addition some drops of myelin are met with. The central substance contains a confused mass of blood corpuscles, drops of myelin of various forms, fragments of vessels ; no distinct nerve-filaments were observed.

The child seemed to be much exhausted by the operation, its temperature was low, the colour of the skin was icteric. The probability, revealed by the operation, that we had taken away a small portion of the brain, which will be found fully corroborated by the pathologico-anatomical description given above, and the certainty that, at all events, a direct connection with the cavity of the skull had been opened, although only through a minute passage, were not adapted to strengthen our previously only faint hope of a successful result, and we already saw before us the prospect of a violent inflammation of the brain, and of the child's speedy death. In so much greater contrast must, therefore, the immediate result of the operation appear.

February 13th.—Soon after the operation the child took the breast, and has repeatedly sucked well. The bowels, too, have acted. The child has slept well.

[From subsequent reports it appears that the healing process went on but slowly, and was not completed until towards the close of March. The cicatrix presented nothing unusual, and was quite movable over the subjacent parts.]

(To be continued.)

THE SUFFERERS IN ST. BARTHOLOMEW'S AND ROYAL FREE HOSPITALS.—The last report says all are progressing favourably except a poor little fellow five years old, who is incurably blind, and "who lies constantly with his eyes to the pillow, as if lost to this world." The out-patients from the explosion, are with a few exceptions, no longer under treatment.

Literature.

NEW EDITIONS.

We resume our notices of new editions of books, commencing with a bulky, well got up volume from America, of which any publisher might well be proud. The work has long been a standard one on obstetrics,[1] and we may therefore be justified in first of all alluding to the form of this new edition, the fifth. It is printed in the best style of art, on fine paper, occupies 760 pages, is very strongly bound in cloth, and the edges are, as they ought to be in all books of this size, properly cut. In a volume of no permanent interest these points are of slight importance, but in a classical work for the study they deserve the attention of publishers. We are glad to say, in this respect, that all has been done to make the book a model, which we hope may be copied. It has been a luxury to peruse it, and a comfort to feel that after doing so it is as new in appearance as ever. Having said thus much, let us turn to the contents of the work. The name of Professor Meigs has long been familiar as a leading American authority on midwifery. Four large editions have preceded this, which seems to have been carefully revised throughout. Besides chapters it is divided into separately numbered paragraphs, 958 in all, which renders it easy of reference. Dr. Meigs throughout addresses himself to the student; yet, where his own opinions are not generally accepted by his professional brethren, he gives both with admirable impartiality. He looks with pride upon his calling, and on suitable occasions does not hesitate to inculcate "good and pure motives" as essential "to the honourable estimation of this department of medicine and surgery." The science and art of obstetrics both receive full attention. The author thinks it is only by the science that the vocation of the accoucheur can be made an elevated one. He says on this point:—

"It is the science of the practitioner that raises him immeasurably above the most dexterous midwives of the land, dexterity which, indeed, does not prevent their ignorance from rendering them unsafe depositories of such important interests as those that concern the conservation of our wives and daughters, and their little children. An accoucheur who is merely dexterous, and who is not acquainted with the scientific parts of his profession, may be, in a manner, superior to the midwife, but in some regards he is inferior; since, to his employment, his sex is an objection, which ought to be waived only in consideration of his scholarship."

Such is the spirit in which this venerable and renowned teacher addresses students, and, we trust, it will be fully appreciated.

The science of obstetricy, according to Dr. Meigs, comprises the anatomy, physiology, and pathology of the reproductive organs, together with embryogeny, the therapeutics and surgery of sexual diseases and accidents, and the disorders of the newly-born infant. Midwifery he calls the "art of assisting women in labour, and of guiding their conduct throughout the following confinement." All these are fully treated of in the volume before us, with a clearness, precision and vigour, that at once charm the reader and command his respect for the talents of the writer. It is impossible to do justice to such a work in a brief notice, and we are fain, therefore, to repeat the mere truism, that it has long been the standard classical work in America, and is favourably known throughout the old world. Those who practice midwifery, and are not acquainted with it, should at once indulge themselves with the new edition, and spend a few leisure hours in the intellectual refreshment of perusing it.

Dr. Meigs was from the first an opponent of the use of anæsthetics in midwifery, and we feel a certain disappointment in having to state that his opinion remains unchanged. He is convinced that "anæsthesia in midwifery has done more harm than good," and, he believes, "its use will decline, and not increase." He thus concludes the section in which this question is discussed—"Having declined for the short remainder of my life the business of a physician, and regarding that circumstance as liberating me from many of the mental bonds that qualify more or less every medical man engaged in the active pursuits of the profession, I distinctly express my regret for the introduction of the anæsthetic methods into the practice of midwifery. I consider that, notwithstanding, there may be some instances in which parturient women should be benefitted by the use of ether, yet, such cases are extremely rare; whereas, the mischiefs arising from the lavish and indiscriminate use of anæsthesia, so tempting as it is, are very numerous and serious."

Yet although Dr. Meigs has discussed the question with great calmness, there is nothing new brought forward to sustain this conclusion. The talk of the drunkness of anæsthesia we put on one side as the mere retort of prejudice. The idea that it is contravening Providence to alleviate the pain of labour, ought only to be held by those who would be willing to carry it to its legitimate conclusion. Yet, we never heard any one say that as it is the ordinance of Providence for men to suffer from disease, so it was presumptuous to try to stem morbid action, nor is it admitted that as it is decreed for men who sustain certain kinds of violence to have their joints dislocated, so the surgeon who reduces the luxation flies in the face of Providence. The one argument advanced by Dr. Meigs is that labour-pain is not pathological, and is, after all, very bearable. But we ask him fairly, is he to be the judge of this? Very easy, indeed, is it for us to look on and say the pain is not so bad, and does not last long; (our author computes that all the pains of a natural labour make up 25 minutes only of actual pain); but women tell a different story—and why should not they be allowed a voice in a matter which to them is much indeed, though to the accoucheur a very little? We remember very well hearing a student trying to sympathize with a woman, by assuring her that the pains were natural, would soon be over, did not last long, and so forth. The answer he received was, he would not talk so if he felt them instead of looking on, and we fancy this is the reply which Dr. Meigs will get from women generally.

The calculation of the time is pretty enough on paper, but will never convince the sufferers. Besides, if it were but of twenty-five minutes—nay, less—if only five minutes—why should that five minutes of agony be endured unnecessarily? In using the word agony, we may be thought to adopt a strong term, but we are sure that mothers would justify us, and they ought to know. We have little space for other points. We can therefore only mention the elaborate chapter on puerperal fever, in which Dr. Meigs, in his most trenchant style, attacks the doctrine of contagion as "injurious to the profession, pernicious to the people, by filling the minds of interested parties with alarm, and as propagating, from age to age, a vile, demoralizing superstition as to the nature and causes of many diseases."

In no instance has the battle between contagionists and non-contagionists been fought with such spirit, as in reference to puerperal fever, and no champion of the non-contagionists is so redoubtable as the venerable Professor of Philadelphia. It is not necessary to express our own convictions here. We mention it because the chapter is quite exciting, and we want to persuade all who have not read this book to take it up. They are then sure to read it through. We shall only name one other chapter with the same view, that on the "Physiology of Reproduction," which is quite exhaustive, and contains many hints of direct therapeutical value. The author follows the views of M. Coste, and adds, too, something of his own. It would be well if every student were well up in the anatomy and physiology of the ovaries, for in such knowledge lies the key to many a case, which has been a sad puzzle to numerous practitioners.

Speaking of the ovaries, reminds us of the second edition of a work[1] on the extirpation of those organs which has just been published by Mr. Hardwicke. We speak of it as on the extirpation, for although it contains a full account of the pathology, diagnosis, and treatment of ovarian tumours in general, the larger and unquestionably the more important part of the work details the author's experience of ovariotomy—an operation of which he was one of the first to undertake, and advocate in recent times, and in which he has been pre-eminently successful. We have read very carefully every page of this book, and compared it throughout with the former edition. We find that it has been thoroughly revised, in some parts re-written, and there is a large amount of additional matter. The book is, in point of fact, about one-third larger. This is to be accounted for by the fact that all the cases successful and unsuccessful in which Mr. Brown has operated since the appearance of the former edition, are related, and the present volume consequently, contains a complete record of his experience of ovariotomy.

1 Obstetrics: the Science and the Art. By Charles D. Meigs, M.D., late Professor in Jefferson College, &c. Philadelphia: H. C. Lea. London: Trubner, 1867.

1 Ovarian Dropsy: its Nature, Diagnosis, and Treatment. By I. Baker Brown, F.R.C.S. 2nd edition. London: Robert Hardwicke.

We have said this edition is carefully revised. We find, in fact, that there is scarcely a page of the old matter that does not give proof of this. Carelessly worded paragraphs now appear more precisely written. Whole sentences are changed in order to render the sense more clear and unmistakable, and considerable changes have been made for the sake of style. The diction is, therefore, more exact, while the book is much more readable. Many inelegancies have disappeared, and we no longer notice any marks of haste in composition.

The chapter on pathology has been largely added to, in order to bring it down to the knowledge of the day. Thus we find the essay of M. Cazeaux, the great work of Professor Courty, of Montpellier, only published last year, and the admirable monograph of Professor Pflüger, have all been consulted in addition to recent British writers.

Following this we have a chapter on the symptoms and cause of ovarian dropsy, which will be useful to the young practitioner. The chapter on diagnosis seems to us greatly improved. Although the general treatment is of inferior interest to the operation, it is very impartially related prior to entering on the subject of ovariotomy.

It will be remembered that, some years ago, Mr. Baker Brown entertained strong hopes that milder measures than that of extirpation might often be useful, and he has himself described some of them—more especially the combination of taping with pressure. Further experience of the almost unhoped for success of ovariotomy has led him to recommend the radical cure in almost all cases of simple cysts. Let us see what this experience amounts to. In the work before us we have the detailed histories of 111 cases of *completed* extirpation, eight of incomplete, seven in which a portion of the cyst was excised, seven of exploratory incision, and three of formation of artificial oviduct. The first edition of Mr. Brown's book only contained forty-two cases, his total up to that time. It will at once be seen how greatly his experience has been increased since the former publication, five or six years ago. As to results,—at first the mortality was very heavy: nearly two-thirds of the patients died. A little later, half only,—still a little later, one-third, then only a quarter, and the mortality goes on steadily decreasing with every improvement. This was noticed by all ovariotomists when ligatures were dispensed with. Again, doing away with the clamp, and dropping the pedicles, tied and cut off close, into the abdomen, in the opinion of some operators, decreased the deaths. The last step in simplifying the operation was introduced by Mr. Baker Brown himself, and consisted in dividing the pedicle by actual cautery, and so avoiding the necessity of leaving a foreign body in the abdomen, yet enabling the operator to close the wound at once. To this the author attributes a very considerable reduction in the number of deaths after ovariotomy. Some of the earlier cases have been submitted to the several medical societies, but all are now here collected,—with this result. Of 49 cases in which the cautery has been used, 41 have recovered, and only 8 died. Of these 8 there were 3 in which the operation could not be completed on account of some untoward complication. Excluding these, we have the magnificent result of 41 recoveries out of 46 operations. Surely the opponents of the operation can have no more to say against it. Out of 46 persons labouring under a disease, which although not immediately fatal, only tends to grow worse and worse, no less than 41 restored to health. The chances are evidently such as not a few victims of disease will be too glad to run. Another very successful operator is Dr. Keith, of Edinburgh. He has lately published his experience. He has operated 51 times; with success, in 40 cases, the remaining 11 having died. We may next contrast the numbers with those of Mr. Spencer Wells. That gentleman stated two or three weeks since, at the Samaratan Hospital, that of his last 44 cases only 6 had proved fatal. Comparing then the results of these operators, it would seem that those detailed above are even more favourable, so that the author of the work before us is, at the present moment, the most successful British ovariotomist. We are pleased that he has given his book so much of a clinical aspect, by merely relating the cases in due order. To those who have not studied the question, it may seem as if such a method would lead to a certain degree of monotony. This effect is however prevented by the conciseness of the narrative—the salient points alone of each case being insisted on. Upon the writer of this notice, who believes himself familiar with every work on the subject that has been published in this country, or on the Continent, the clinical record, under consideration, has produced a strong impression. An honest perusal of it, by those few who, at this day, condemn ovariotomy, might well change their views.

We have next to announce that a second edition of Mr. Skey's six lectures on Hysteria[1] has reached us. It is a reprint of the book noticed by us some time since, and, therefore, does not require further consideration. We must, however, repeat our protest against Mr. Skey representing that the bulk of the profession is opposed to tonic treatment, and in the habit of bleeding and otherwise depressing to excess. In most of our large cities, perhaps, the other extreme is more likely to be reached, and Mr. Skey seems to forget the great changes that have taken place in practice since he was young. He does himself scant justice in representing that his own teaching (as well as that of others), during the last half century, has had but little effect. We beg to remind him, with the greatest respect, that a generation of his own pupils are now in practice, scattered throughout the country, and therefore it is almost impossible that the lessons he so long ago inculcated, should not have brought forth fruit in a way to render his picture of the actual practice of the profession no longer true.

The only possible plea for such a picture is, that many text-books and manuals continue to teach the same therapeutical methods as their predecessors, but text-books change very slowly, and cannot in any case be taken to represent the living voice of the profession. At any rate, there is now no neglect of stimulants and tonics. We do not think these agencies are in the least danger of being omitted, and sometimes are inclined to fear that they may be used too freely. Altogether, then, we fail to see the opportuneness of Mr. Skey's warning, and the need for his urgency in pressing what he calls the "treatment of disease by tonic agency."

Under the title of the "World-Wide Library," Messrs. Routledge and Sons are publishing a series of standard works, at 6d. each. In this form they have brought out for that sum a complete and well-printed edition of De Quincey's "Confessions of an English Opium Eater." No one can now say that that remarkable work is beyond his reach.

We have still several new editions on hand, but must let them remain another week. This article is already so long, that we will close it by noticing a little book which, not being strictly professional, demands but few words at our hands. It is the eighth edition of Mr. Streeter's little work on jewellery,[2] which, if not necessarily interesting to our medical brethren absorbed in the cares of practice, will be heartily welcomed by their wives and daughters. It initiates the reader into the mysteries of carats, and the value of the different qualities of gold, gives hints to purchasers that may save them much money, and contains some curious notes and statistics about the value of gold in different countries. The chapter on how jewellery is made by machinery, is illustrated by the dies and presses that are used in the author's establishment.

CLYDESDALE DURING THE GLACIAL PERIOD.—To sit on one of the headlands of the Clyde and watch the myriad ships as they come and go from all corners of the earth; to trace village after village, and town after town, dotting the coast-line far as the eye can reach; to see the white steam of the distant railway rising like a summer cloud from among orchards, and corn-fields, and fairy-like woodlands; to see far away the darker smoke of the coal-pit and the iron-work, hanging over the haunts of a busy human population; in short to note all over the landscape, on land and sea, the traces of a power that is everywhere changing the face of Nature, and then to picture that earlier time when these waters had never felt the stroke of oar or paddle, when these hill-sides had never echoed the sound of human voice, but when over hill and valley, over river and sea, there had fallen a silence as of the grave, when one wide pall of snow and ice stretched across the landscape; to restore in imagination the dull, sullen glacier threading yonder deep Highland glen, which, to-day, is purple with heather, and blithe with the whirring of grouse and woodcocks; to seal up the Firth once more in ice as the winter frosts used to set over it, and to cover it with bergs and ice-rafts, that marked the short-lived Arctic summer; to bring back again the plants and animals of that early time; and thus, from the green and sunny Clyde, with all its human associations, to pass at once, and by a natural transition, to the sterility and solitude of another Greenland, is an employment as delightful as man can well enjoy.—*North British Review.*

COTTAGE HOSPITALS.

SINCE Mr. ALBERT NAPPER established his "village hospital" at Cranley, in Surrey, these unpretending institutions have grown rapidly in public favour, and may now be said to have established for themselves a position of usefulness which few anticipated they would attain. It cannot but be a source of gratification to Mr. NAPPER to find himself the pioneer of a scheme so beneficent and successful, and his pamphlet[1] referred to by every one desirous of founding one of these charities. Within seven years of the Cranley Hospital being founded, 16 similar institutions were at work, and 67 others in the course of being established. The number is being constantly added to, and yet there is doubtless ample scope for further increase. Mr. H. SWETE has lately suggested the propriety of organising a *National Cottage Hospital Association* to aid in establishing these institutions; frame a common set of rules for their management; diffuse adequate information about sick diet, cookery, and nursing; supply plans for building and furnishing; and otherwise aid by money and advice wherever they may be required. The scheme is, perhaps, a little ambitious, but once in working order would, no doubt, greatly promote the object in view.

The many advantages of Cottage Hospitals have been summed up in a recent pamphlet by Dr. WARING[2], who advocates their extension and lays down rules for their management with earnestness and precision. We refer the reader who may desire information as to details to both this and Mr. NAPPER'S work, and propose to devote this article to the consideration of one or two principles of the highest importance. First of all, then, as to the surgeon of the institution. It seems to be taken for granted that the office must, in every case, be a gratuitous one, and while all London charities are thus worked, perhaps it would be hard to insist on such unpretending ones commencing a more just system. But, with regard to who should be the Medical Officers, it seems to have been too hastily assumed, in some quarters, that the care of the hospital must be confided to one surgeon. Here and there this may be well, but, as a rule, we venture to express an adverse opinion. There is no reason at all why all the practitioners within a moderate distance should not be on the staff. To give the office to one is to place the others at a disadvantage, and necessarily to encourage the establishment of rival hospitals. It is urged by Dr WARING that every medical man in the neighbourhood may send in suitable cases, perform an operation, and take any fee that may become due for it from the Poor-law Guardians. We, however, dispute his axiom that, "as a matter of necessity, one medical man must be surgeon or medical attendant in ordinary;" and we ask him to candidly reconsider this point. He can only desire the utmost good feeling to prevail between all the medical men of a district, and this we think would be best secured by making all equal in authority, and, therefore, equally interested in the welfare of the charity.

We have yet another fault to find with some of the promoters of these excellent institutions. They would impart to them a sectarian aspect by endowing the clergyman of the parish with authority over them. Far be it from us to deny that the parish clergy, as a body, are always ready to aid by their influence every good work; but this is a virtue by no means confined to the clergy of the Established Church, and to utterly ignore the non-conforming bodies is to show either sad ignorance of the condition of the country, or a still sadder narrowness of spirit.

Here and there, it may be, a small district may be found in the rural parts of England, where the English Church is so much in the ascendant that other religious bodies scarcely make their existence known; but these, in general, are not the places where progress is being made, and where activity is perceived in establishing all kinds of good works—cottage hospitals amongst them.

We would therefore urge a much broader basis in this respect than any one has yet proposed. We are gravely told that the spiritual supervision of the hospital *naturally* devolves on the clergyman of the parish, and are advised to make him the general manager—a proceeding likely to lead to great dissatisfaction, for there is always danger that the assumption of the priest, on the one hand, may engender discord and disgust the thoughtful, though not necessarily irreligious; or, on the other hand, that the best intentions may only develop hypocrisy and cant.

Even Dr. WARING, whose work is characterised by great good sense, falls into the common snare, and remarks—

"In most hospitals there is a rule to the effect that patients of all religious denominations and persuasions may be attended by their respective ministers, at such times as may be most convenient to themselves, or may be fixed upon by the manager. This does not imply the right of such minister to hold a *public* service of any kind, and when at the hospital he should confine his attention to the individual patient to whom the visit is paid.

"With this exception, no one should be allowed to visit the patients with a view to their spiritual edification, excepting at the request or by the special permission of the clergyman who has charge of the spiritual wants of the hospital, and who will make all requisite arrangements to meet them."

Now, we can be no parties to such rules, which savour of anything but liberality. Why, the Surgeon may be a dissenter (Roman Catholic or Protestant) from the Established Church, and yet his steps are to be dogged by a priestly manager, who may pervert the charity which depends on medical skill to the purposes of the lowest sectarianism. Away with this dependence on clerical aid. Let the hospitals be as unsectarian as the science by which they are sustained, and let not the Profession hand over its prestige and its honour to the keeping of the parish priest.

1 On the Advantages derivable by the Medical Profession and the Public from Village Hospitals.
2 Cottage Hospitals: their Objects, Advantages, and Management, by E. J. Waring, M.D. London. 1867.

THE VACANT CORONERSHIP.

THE Coronership for the western division of Middlesex, which, as we noticed last week, is vacant through the untimely decease of Mr. BIRD, is likely to be very hotly contested, and we regret to add that unless the Profession unite to support one of the medical candidates, there is a likelihood that a lawyer may creep in. We think it, therefore, our duty to call on the Profession once more to use its united influence to uphold the principle that only a properly educated medical man should be entrusted with the duty of presiding over a court for enquiring into the cause of a person's death. It is a principle which the profession has a direct interest in supporting, and which only requires to be stated to gain the adherence of the majority of people. It is one, therefore, which our brethren may be called upon in a case like this to urge upon all their patients, who may have a voice in the matter. But assuredly, division in our own camp is likely to endanger it ; and we, therefore, regret to see too many candidates. Dr. HOLT DUNN, with a high-minded regard for his profession, and a generous appreciation of the claims of another candidate, has at once withdrawn from the contest upon which he had entered, and will use his influence in favour of Dr. HARDWICKE, who is already known favourably as the efficient deputy-coroner for the central division of the county, and as an able medical officer of health.

We also hear that Dr. WHITEMORE, who had great prospects of wide professional support, has decided not to go to the poll. This would leave Dr. HARDWICKE alone in the field to represent our profession (for, although there was a wish to see the other scientific men we mentioned last week brought forward, there was never much prospect that either of them would accept the office), but for the appearance of two other candidates, viz., Mr. GEORGE BROWN and Dr. DIPLOCK. It remains, then, for these three gentlemen and their friends to discuss the claims of each with a view of reducing the number of candidates. Division of the medical interests will infallibly advance those of the legal candidates, and we therefore earnestly hope that a friendly arrangement will be made.

Dr. DIPLOCK is, we hear, a gentleman of large fortune, and who could not desire the appointment for the sake of its scanty emolument. Could he not in any way coalesce with the friends of Dr. HARDWICKE, whose experience as a deputy-coroner and officer of health endorse the favourable opinion of the Profession as to his qualifications.

Mr. G. BROWN is a practitioner of several years' standing, and he holds appointments which, to a certain extent, may be incompatible with the Coronership. He is, of course, most competent to pronounce which he would prefer; but the emoluments of the Coroner for Western Middlesex are so slight that we believe the late Mr. BIRD, who held the office for five years, was unable during that time to recoup himself the outlay it cost him to obtain it. It may very likely, therefore, turn out that the office is not worth seeking by so well-established a practitioner as Mr. BROWN. Should this be so, we feel sure that Dr. DIPLOCK, as a man of fortune, will also be likely to retire, and thus that there may be some hope of securing the post to a member of the Profession. There is no time to lose. The lawyers are actively canvassing, and one of the two is almost certain to go to the poll. Only a strong, united effort will avail, and we repeat our hope that every medical man possessed of influence will at once exert it in behalf of his Profession.

It is useless to indulge in platitudes about abstract principles unless we are prepared, on occasions like this, to enter the lists with spirit, and bring all our forces to bear on the issue of the particular case.

While we have been pleasing ourselves with high-flown declamation, other bodies have been busy organising, and the consequence is that while most other portions of the social fabric make their influence felt, the Medical Profession is constantly regretting its position and but feebly expressing its rights. Let us on all occasions be found ready and active, and our power will at once be recognised. This vacancy is but a case in point. First let us select our man ; then by one united effort we may assert our just influence as triumphantly as we did when we placed Dr. LANKESTER in the position of Coroner for the Central Division of the same county.

FEVER NESTS.

THERE can be no doubt that carelessness in some cases, and ignorance in others, are the cause of many, if not most, of the diseases that "flesh is heir to," at all events, of their ascendency. If all knew the existence of danger, and were determined to take every means of avoiding it, we should hear much less than we do of the prevalence of disease in certain localities where it has a marked effect on the death-rate. But there is a degree of recklessness oftentimes with regard to health, which is hardly ever witnessed in other concernments affecting human nature. Men run risks in this respect which would justly terrify them in liabilities far less prejudicial to their well-being. We can only account for this from the fact that they do not think, but pursue their ordinary course unconscious of those surroundings which threaten their very existence. Perhaps it is not to be wondered at that such should be the case with the poor and uneducated, whose utmost energies are taxed to procure the means of subsistence for themselves and their families. In the present day, however, it is matter of surprise that those above them should be equally negligent when they know better, and may become, if not to the same extent, yet, in some instances, victims of their indifference. They, at least, ought to consider that while the sun is shining brightly over head, and nature has on her gayest dress, while the earth teems with plenty, and Providence seems lavish of its bounties, an insidious enemy may, all the time, be lurking in the vicinity of their dwellings. A few cottages closely packed together, and badly ventilated, with insufficient drainage, and cesspools filled with night soil, and decomposing matter of different kinds, making its way through the ground and tainting the well from which the water-supply is obtained, though, to a careless eye, in the splendid summer day all seems fair, may be generating a fever which may spread beyond the immediate spot, and reach those whose condition leads them to suppose that they are altogether exempt from such danger. We refer now more particularly to Winterton, where typhoid fever had long prevailed, and which was visited by Dr. THORNE for the purpose of investigating the cause. He found there all the strange peculiarities we have named, and a great many more amply sufficient to account for the origin and continuance of the epidemic. It is to be feared that this is by no means an isolated case. We could give our own testimony in reference to a village we had occasion to visit last summer. We could tell of bad water, bad drains, disgusting

smells in the midst of a state of perfect unconcern. We shall, however, only state it as our conviction that sanitary measures are not by any means so extensively and persistently carried out as they ought to be. An eruption of cholera sometimes awakens us to our duty; but there is a necessity at all times, and in all places, for watchfulness, which renders it incumbent upon all in their several localities who wish well to their species to seek out, and, if possible, remove whatever may be detrimental to the general health.

As tending to promote the cause of sanitary reform, we are glad to see in the local newspaper a reprint, in full, of Dr. THORNE'S report to the Privy Council on the epidemic at Winterton.

THE MEDICAL BENEVOLENT FUND OF ENGLAND.

THE Committee of the Medical Benevolent Fund has just presented its report, and as the quiet, unobtrusive character of the operations of this excellent charity prevents it from being so generally known as it deserves, we venture to bring it to the notice of our readers. The main object of the Fund is to relieve temporary distress among members of the Profession or their families, arising from illness or misfortune, and during the year 1867, £902 has been thus applied, the number of cases assisted being 106. The Committee meets once a month, to receive and consider applications, and if the facts are duly authenticated, and the distress is found to be real, a sum of money is at once voted. When the applicant can be reached by any Member of the Committee, he is usually visited, and the value of the donation is often enhanced by its judicious distribution, while the personal investigation gives additional security that it is properly bestowed.

There is also an Invested Fund, which maintains 30 annuitants, who must be over 60 years of age. There cannot be more legitimate objects of compassion than the aged, afflicted, and unfortunate of our own Profession, and a charity which affords timely aid to such in the hour of need, without imposing the labour of a canvass, which to the most helpless and friendless is an impossibility, or necessitating publicity, from which the most meritorious often shrink, deserves our warmest support.

The Medical Benevolent Fund was long associated with the name of the late Mr. Toynbee. Since his death, Dr. Sieveking has held the office of treasurer, and he is now succeeded by Dr. Hare. Dr. Broadbent has for several years given his services as Honorary Secretary, and he is now joined in that office by Dr. Thorne. It is no light task which these gentlemen undertake, and we trust many of our readers will send their names to one or other of them as subscribers.

Notes on Current Topics.

Is Consumption Catching?

THE term catching is better than contagious or infectious, for it includes both, and does not lead to mistakes. Those who have seen much of country districts must be aware that a belief in the liability of one member of a family to catch consumption from another is very general. Many a village doctor has tried to laugh his patients out of their belief, and failed.

On the Continent, the notion is much more common, especially in the south. A few years ago, an English peer, whose lady had died in Italy, was called upon to defray the expense of rebuilding the portion of the hotel she had inhabited. A lady, who was for many years under our care, was, while on a visit at Naples, attacked by a cough. The Princess, in whose palace this patient was staying, begged her to keep in one wing, lest it should have to be pulled down, and the patient's gravity was imperilled by the footman bringing everything into her room, and rapidly disappearing as if in mortal terror. Moreover, he handed her letters to her at the end of a silver rod more than a yard long, which she innocently supposed to have been surreptitiously obtained from a church, where it might have been used to light the candles. The people were so afraid of catching the English disease.

Along the Riviera the same belief is prevalent. Some of the people will assure you positively that consumption was unknown until the English brought it; and this is not in the towns alone; but those who understand the dialects and scale the mountains will be told the same by the peasantry. We have heard them argue, that the towns frequented by our countrymen in winter, were very unfortunate in spite of the increase of wealth, on account of the inhabitants being decimated with the English disease. We turn from these popular superstitions, which have so long been ridiculed, to sober seekers after truth in medicine, and what do we find? One tells us that the disease may be propagated by inoculation. Another says that under certain circumstances it may be communicated by one person to another. Then Dr. Budd, of Bristol, a name which is a tower of strength, startles not a few with a statement that consumption is neither more nor less than a zymotic disease —a sort of contagious fever. He is busy arranging his arguments on the subject, and so far as wide-spread prejudice goes, the above facts, for which we can vouch, show that the people will be on his side, although he will find it a much harder task to convince the doctors.

There is no occasion for us to enter here upon the difficulties that surround this notion. The work has already been partly done by able contributors to our pages, and is sure to be continued from time to time.

A Question for the Government.

THE late Government, in April and May, 1866, had charcoal filters fitted to the cisterns which contain the water drunk by the soldiers that garrison the Tower and those in Regent's-park Barracks. The present Government has had these filters removed. Wanted to know—why?

Post-mortem Detraction of a Professional Brother.

SOME time ago we took upon ourselves to reprove a contemporary for making the obituary of an esteemed deceased practitioner the vehicle of its wrath against specialists, and of unjust personal attacks. The charge was replied to in a statement we reprinted. The same journal has again laid itself open to the same complaint. The death of Mr. Salmon is now made the text on which to preach another sermon on specialism, the point of which is that, in the opinion of the select few who rule the shifty politics of the British Medical Association, "the success of St. Mark's Hospital was of unfortunate omen, and has since borne bad fruit in encouraging similar enterprises." We are not about to enter the lists in defence of St. Mark's. That hospital has borne fruit with which St. Mary's might, at one time,

have aspired to divide the honours, had not the latter charity been so jealous as to require its staff to give up all connection with the special institution. And yet the ambitious western hospital evinces a curious annoyance with its rival in one branch of surgery, and brings to bear all its peculiar influence with the association to crush it. The effort is, however, useless, for the public has pronounced on the question, and supports special hospitals as well as the larger charities, and that in spite of the active and unscrupulous crusade against them. Neither do we object to any fair opportunity being taken by any set of men to promote their political ends, or even to further their own interests. We do, however, object, and that very strongly, to obituary notices being made the medium of such attacks upon the honour of professional men and their motives in establishing and serving charities that have been supported by the public. There is something unseemly in seizing upon every such opportunity to indulge in political cant, and ventilate the narrow shibboleth of a faction. In the name of common decency, we once more protest against such tactics. Is our profession so lost to all propriety as to permit journals that aspire to represent it, to indulge in such diatribes over the coffins of its members? We trow not. Even the bitterest enemies of specialism will be sensible that their views cannot be forced upon others by the terrors of post-mortem denunciation. Thus, to make death serve as the stalking-horse of a party, is as incongruous as to propose a quadrille at a funeral, or to dance a hornpipe over a newly-made grave.

The Fever at Terling.

Those who know Terling (and our own acquaintance with the queer little Essex village dates from a dozen years ago) will not be surprised that the epidemic which we lately noticed as prevailing there has been very fatal. Our contemporaries have evinced a, perhaps laudable, desire to publish the facts, but their haste has, in some cases, outrun their information. The partial accounts that have found their way into print must, therefore, not be allowed to do duty for the report of the Medical Officer sent by the Privy Council to investigate the circumstances, and which will, no doubt, be forthcoming in due course. As a proof of this, we may name that Lord Rayleigh's housekeeper, said by one of the medical journals to have died of the fever, is still in excellent health. We are much mistaken, too, if some of the statements so hurriedly printed will not be found, on the publication of the official investigation, to be exactly the reverse of fact.

Cannes and Llandudno as Winter Resorts.

Dr. James Nicol, the Medical Officer of Health for Llandudno, in North Wales, communicates to the *Times* of January 16th, some interesting matters respecting the winter temperature at the above well-known and much-frequented watering-place.

An examination of meteorological tables, kept at Llandudno, and at Cannes, in the South of France, during last December, reveals the rather surprizing fact, that for the month of December last, Llandudno was warmer than Cannes by 3·5 deg.; and that it also enjoyed a temperature more equable, and of smaller range.

On examining the tables, it is noted that the mean temperature of the month of December last, at Cannes, was 39·6 deg., the range for the month 23 deg., and the greatest range between any two consecutive days 18 deg. At Llandudno the mean temperature of the same month was 43·1 deg., the range for the month 18·2 deg., and the greatest range between any two consecutive days 16 deg.

The excellence of the climate of Cannes and the South of France, as a winter resort for a very numerous class of invalids, is now pretty well proved and established, and for those who have not the will or the means to go to so great a distance from home, it will be welcome news to learn that there is a place not difficult of access, in the British Isles, where they can enjoy a warm and uniform winter climate.

Poisoned by Goose-Grease.

The newspapers have published an account of an inquest held last week upon the body of a woman who was alleged to have died after eating a poisoned goose. All the persons who partook of the goose in question were attacked with vomiting and purging. A careful analysis of the contents of the stomach of the deceased was made by Professor J. E. D. Rodgers, of the London Hospital Medical College, who stated at the inquest that he had also examined a portion of the goose fat, cooked and uncooked, and could not detect a trace of any poison, either vegetable or mineral, but it was a well-known fact that the fat of geese occasionally contains poison. Dr. Buchner has recorded cases of that description. The fat contains an acid, and he (Professor Rodgers) had no doubt that the goose in question contained a portion of that acid, which caused the death of the deceased. There would be fat in the giblets. The stomach gave indication of an irritant poison. If the goose had eaten any vegetable poison he should have detected it. The Coroner (Dr. Lankester) enquired whether the close way in which the geese are packed has a tendency to generate the acid? Professor Rodgers replied—Most decidedly; very disagreeable effects are often produced by animal and vegetable food that has been closely packed. Salmon was, also, very often kept by fishmongers until it was bad, and then dipped in "Condy's fluid," which took away the bad smell, but it was dangerous to eat it; it caused vomiting and purging. He knew of three cases of that description. The Coroner remarked that very bad effects were often produced by the eating of animals that had been closely packed, and he instanced a case that occurred in the family of the late Sir Benjamin Brodie, sickness being caused by the eating of Canada grouse. The poulterer gave evidence that the goose was a very fine one. It came from Lincolnshire, and was not closely packed. He had been in business 25 years, and never heard of any one being poisoned by a goose or other poultry. A verdict was recorded that deceased died from eating poisoned goose. We are glad to state that the jury recommended the magistrates to grant Professor Rodgers a higher rate of payment than the Coroner has power to order, which is altogether an inadequate fee for analysing the contents of the stomach.

Country Wells.

Professor Attfield has published in the *Times*, an important letter, provoked by the epidemic at Terling, in which he draws attention to the evil of having the well and drains close together, as they too often are in country places. We have ourselves had occasion to speak of the practice of builders, who, for the sake of lessening cost, will sink wells in proximity to drains. Dr. Attfield concludes his letter with the following simple test for water:

—"Half fill a common water-bottle, cover its mouth with the hand, violently shake for a minute, and quickly apply the nose. If nothing unpleasant is detected, tightly cork the bottle, set it aside in a warm place at about the temperature of one's body for a couple or three days, and repeat the shaking, &c. Water of very bad quality may thus be recognized without the trouble and expense of analysis."

Dr. Richardson's Practical and Experimental Lectures.

Dr. Richardson gave his first lecture of the present year on the 14th, at No. 12, Hinde-street, the subject of anæsthesia being still continued.

A very curious and interesting experiment was performed by freezing, with the ether spray, the brain of a pigeon. In a short time the bird lay on the table in a state of perfect anæsthesia, and Dr. Richardson told the audience that the brain, if examined now, would be seen of a snowy whiteness, and quite bloodless.

After a few moments the pigeon began to recover, *gradual reaction* taking place; then came the most striking part of the experiment, for Dr. Richardson showed that by causing *rapid reaction* the process of recovery was interrupted, and anæsthesia again induced. The way in which rapid reaction was effected was by applying the warm finger over the skull, and after this had been done for a very brief period the bird again fell over in a state of complete narcotism. The brain, if examined in this stage of sudden reaction, would be found quite dark, as if the veins were in a state of extreme varicosity.

Since the last lecture Dr. Versmann has obtained a new anæsthetic by the action of oxide of manganese and sulphuric acid on methylic alcohol. Methylal was the name given to this new liquid, and its chemical composition stated to be $C_3 H_8 O_2$, sp. gr. ·855, and boiling point 108° F. Methylal resembles, in some respects, the formiate of ethyl, which has a chemical composition of $C_3 H_6 O_2$; sp. gr. ·940, and boiling point, 130° F. Neither of these bodies are safe anæsthetics, as they appear to be decomposed in the animal organism, and the resulting compounds are dangerous to life. Hence, is seen the importance of using as anæsthetics bodies which do not decompose in the system, but pass from it unchanged, just as we observe the chloride of ammonium, when taken internally, to pass out of the body quite unchanged in the urine.

If an anæsthetic vapour becomes decomposed in the body, there is the danger that bodies actually poisonous in their action may be produced by such decomposition.

Towards the conclusion of this lecture allusion was made to the observations of Dr. Sedgwick on the mechanical way in which various anæsthetics mix with, and diffuse among, the blood corpuscles, and this admixture of the anæsthetic with the blood was demonstrated under the microscope. There were also exhibited tubes containing blood that was mixed with different anæsthetics.

At the next lecture, on February 11th, Dr. Richardson purposes to continue the subject of the influence of anæsthetics on the blood, and then to take up some highly interesting and important matters connected with their action on the brain.

The Public Health.

The annual rate of mortality in the large towns of the United Kingdom in the week ending on the 11th instant, was 28 per 1000 persons living. In the separate towns the rate was 26 per 1000 in London, 25 in Edinburgh, and 32 in Dublin; 24 in Bristol, 28 in Birmingham, 33 in Liverpool, 35 in Manchester, 30 in Salford, 22 in Sheffield, 29 in Bradford, 29 in Leeds, 30 in Hull, 25 in Newcastle-on-Tyne, and 33 in Glasgow.

There were 1574 deaths in London registered during the week. This is 225 less than the average number for this week of the year, corrected for increase of population.

There were 273 deaths from zymotic diseases, the average number being 364. Measles killed 48 persons, scarlatina 49, whooping-cough 49, typhus 25. Of diseases of the chest we notice 187 deaths from phthisis, 294 from bronchitis, 91 from pneumonia, and 81 from cardiac disease.

The highest day temperature of the week at Greenwich, was 35·9 deg. Fahr. The lowest night temperature was 25·0 deg. The entire range of temperature for the week was, therefore, 10·9 deg., but it was much less during the latter than the earlier half of the week.

SCOTLAND.

In the eight principal towns of Scotland—Glasgow, Edinburgh, Leith, Dundee, Aberdeen, Paisley, Greenock, Perth—the deaths of 2379 persons were registered in the month of December; allowing for increase of population, this number is 90 under that for December of the last ten years. 44 per cent. of the deaths were of children under five years of age. The zymotic (epidemic and contagious) class of diseases proved fatal to 480 persons, constituting 20 per cent. of the mortality; that rate was scarcely exceeded in any of the eight towns. The most fatal epidemic was scarlatina, which caused 131 deaths, or 5·5 per cent. of the mortality; in Edinburgh, 9·2. Typhus was the next most fatal epidemic, having caused 119 deaths, or 5 per cent. of the total mortality. The deaths from inflammatory affections of the respiratory organs, with consumption, whooping-cough, and croup, were 900 of the whole 2379. There were 71 deaths from violent causes, two of them suicides; four deaths resulted from intemperance. The deaths of five women were registered who had passed their 90th year; the oldest was an unmarried woman, lately a domestic servant, aged 98. The births registered were 3106; this number was exceeded in the month of December in 1864 and 1866. The marriages were 840, which, allowing for the increase of population, is 20 under the average of the month for the last ten years. The month began with a severe storm, but the weather on the whole was moderate, if not absolutely fine, the barometrical pressure having been high, and its variations small; the mean temperature, 39·7, was slightly less than for an average December, and the quantity of rain and wind considerably less. The greatest depth of rain was at Glasgow, 4·88 inches; and the least depth at Dundee, 0·95 inch. The prevailing direction of the wind was W.N.W.

IRELAND.

The return just issued records 18,549 deaths registered in Ireland in the third quarter of 1867, being in the annual proportion of 13·4 per 1000 of population. Scarlatina prevailed and was endemic in many districts. In Brookeborough, Lisnaskea, nearly one-half of the deaths were caused by this disease. There were only two fatal cases of small-pox during the quarter, and the registrars furnish evidence in support of the benefits arising from the Compulsory Vaccination Act; in some districts there

had not been a case of small-pox for three years. Whooping-cough was very fatal in some parts of Ireland; and typhia, or typhoid fever, was more prevalent than typhus. A fatal case of fever occurred in the Rathcoole district, Celbridge, accompanied with ecchymosis, or dark patches of blood under the skin; the duration of illness being only 14 hours. At Clonmany, Inishowen, the people suffered from chest affections, which the registrar attributed to their occupation; he states that they "are up all night gathering seaweed." At Youghal, Clashmore, fever and malignant typhus overran a whole country side, until a panic seized the population, and even the schools were closed. This outbreak of fever was attributed to the close proximity of the invariable dunghill to the cabin of the labourer. The Registrar-General, however, reports that on the whole the health of the people has improved within the last few years, and many sanitary improvements have been adopted. Among the exceptions to the general progress of hygienic measures may be mentioned Waterford city, where the sanitary arrangements are reported to be the worst in Ireland. The fatal epidemics were confined to a few districts; employment for labourers was abundant, and wages were good. The registration of deaths in Ireland continues to be very imperfect, and attention is directed to certain districts where the deaths registered during the quarter ranged from an annual ratio of about one in 100 to one in 200 of the population. The birth-rate of the quarter was 24·7 per 1000 of population. The number of births registered during the quarter was 34,248, and the number of emigrants was 18,475; a decrease, therefore, of 2776 appears to have taken place in the population of Ireland during that period. In the corresponding quarter of 1866, the emigrants numbered 19,640. The number of marriages registered in Ireland during the second quarter of 1867 was 5166; in the corresponding quarter of last year the number was 6045. Of the 5166 marriages, 3101 were between Roman Catholics, and 2065 were between Protestants. The mean temperature of the air for the quarter ending the 30th of September, 1867, was 58·5 deg. The rainfall measured 6·058 inches. The mean height of the barometer was 29·786 inches.

Dr. John Taylor, M.R.C.P., relates in last Saturday's *Lancet*, a case of Cæsarian section, occurring in his practice, and in which the double success of saving mother and child has been attained. The operation was performed by Mr. Baker Brown, on the 28th of December last, at the London Surgical Home. Messrs. Hubbard, Watts, and Strange, and Dr. Holt Dunn, as well as Dr. Taylor, were present, and assisted the operator. All these gentlemen concurred in the necessity of the operation.

The heads of the Army and Navy Medical Department, are likely to get a K.C.B. In no other country is the Profession left without distinctions to the extent it is in our own.

We have had a letter this week from Abyssinia, from a medical man on duty with the forces. He speaks encouragingly of the climate and of the provisions made for the comfort and health of the troops.

The French Hospital in London is laying a broad foundation, and will probably, in a short time, be in a condition to extend its sphere of action.

The prize of £100, offered by the Ladies' Sanitary Association, for the best essay on Vaccination, has been awarded to Dr. Ballard, Medical Officer of Health for Islington, a Graduate of the University of St. Andrews. The adjudicators were Dr. Richardson, Dr. F. C. Webb, and Mr. J. F. Marson.

The winter weather in the south of Europe, on which we commented last week, has become less severe, simultaneously with the break up of our own frosts.

Society Proceedings.

SURGICAL SOCIETY OF IRELAND.

Dr. Adams, President of the College, in the Chair.

This Society met on Friday, January 3rd, at the Royal College of Surgeons.

Dr. Frank Thorpe Porter read the following paper:—

PENETRATING WOUND OF THE CORNEA.

Mr. President,—I submit for your consideration a case of "foreign body in the right eye-ball," which presents some points of interest. The patient, an agricultural labourer, aged 25, called on me on the 8th of last June. He made the following statement:—"Towards the close of last March he was at work on a farm, and was employed to repair gaps in hedges. During the performance of this work a thorn branch came in contact with the right eye. He had to leave off work owing to the severe pain. He was blistered, poulticed, and purged, but experienced no relief. The pain soon extended over the right side of the head. Owing to the severity of the inflammation, the closing of the right eyelids could with difficulty be accomplished. The power of sight was lost in the right eye, and that in the left became weak after the lapse of some weeks. He slept but little, and became very much emaciated in appearance. He was in a state of dreadful suffering for almost three months, but he occasionally obtained relief by means of anodyne embrocations. He followed his employment, but often had to desist owing to severe paroxysms of pain." When I examined the eye it was one mass of destructive inflammation. The conjunctiva and sclerotic were intensely congested. The cornea was ulcerated and covered with opacities. The iris was in an advanced state of inflammation, and was attached to the cornea at the pupillary margin. The pupil was contracted and irregular in outline; the eye-ball protruded beyond the lids. I perceived an ulcer on the cornea over the inner edge of the pupil. I suspected that a foreign body was lodged in this ulcer, and on passing in a forceps I extracted a large thorn. I ordered a zinc collyrium. This caused the congestion to disappear in two days. I prohibited all stimulants. I substituted atropia for the zinc lotion, and prescribed frequent blistering and purging. The blisters were applied to the temples, behind the ears, and to the nape of the neck. In one week the acute symptoms subsided. I then administered tonics, with alteratives and with absorbents, but I avoided the use of mercury, for reasons I am prepared to explain. In three weeks' time the sight of the injured eye improved, and the patient could distinguish between light and darkness, and in six weeks he could distinguish large objects. In two months the opacities on the cornea commenced to disappear, and the pupil assumed more of its natural appearance. When I last heard from the patient he was able to distinguish small objects with the aid of a good light. He is now strong and active, and suffers no pain or any inconvenience at his work. I have suggested to him the prudence of consulting a specialist, but there were difficulties in the way of such a step, as my patient resides at a long distance from Dublin. The case has turned out well, considering the extensive injury and the length of time the foreign body had been lodged in the eye-ball.

The President observed, that as two more communications relative to the eye were to be made, he thought it advisable to hear them first, and then discuss the three.

CALCIFICATION OF CRYSTALLINE LENS AND VITREOUS BODY.

Dr. Croly said that, about a month ago, having finished the demonstration of an orbit in the College School, he took

out the eye-ball for the purpose of showing the vitreous body, and the position of the crystalline lens. On opening the sclerotic, the vitreous body was absent and the cavity empty. A well-marked bony plate occupied the situation of the retina. On examining the crystalline lens he found it also converted into a calcareous deposit.

Dr. ARCHIBALD H. JACOB communicated a

CASE OF SUB-CONJUNCTIVAL DISPLACEMENT OF THE LENS, WITH COMPLETE TRAUMATIC MYDRIASIS, REMEDIED BY MECHANICAL MEANS.

Dr. JACOB said a double interest attaches, Mr. President, to the case which I am about to bring under the notice of the society, firstly, as an instance of a very rare and remarkable injury of the eye; and, secondly, as an illustration of a highly successful substitution of mechanical adaptation for the natural functions of which the eye had been deprived. I need not detain the society with any history of the case prior to the time when it came under my notice, as such a narrative is not relevant to the points to which I wish to direct its attention.

On the 6th of May, 1866, exactly a year before I saw him, the patient, T. K., a farmer in the north of Ireland, while superintending some works on his own land, was accosted suddenly from behind, by a person who was at the moment about to lay a hand on his shoulder. Turning round quickly his right eye met the out-stretched hand of the speaker, and a very violent injury was then and there inflicted with the thumb-nail. The character of the injury as it presented itself subsequently, I will presently explain. It was followed by pain, described by him as that caused by "smoke from unseasoned timber," and by total blindness, which was looked upon as irremediable, and which subsequently only recovered in a very partial degree.

For this injury he was substituted to the usual depletory treatment for seven weeks, at the end of which period the supervening inflammation had, in great measure, subsided, without any marked improvement in the sight. Of the appearance presented by the eye, or the injury diagnosed by his medical attendant, he could give me no information.

About seven weeks afterwards he was attacked with sympathetic ophthalmitis in the left eye, for which he was treated on the most vigorous plan by repeated leeching, the application of belladonna, and an almost heroic course of mercury. This treatment appears to have had no effect whatever on the sympathetic inflammation, for on presenting himself to me, which he did in the hope of saving that eye, it was hopelessly blind. the pupil closely adherent, the iris tremulous and the vitreous humour softened. After satisfying myself of the conditions, and giving it as my opinion that vision was irremediably destroyed, I asked him about the other eye. He replied, "Oh, there is no use looking at it, it was lost long ago."

On further inquiry, I ascertained the circumstances under which it had been lost, and learned, further, that since the treatment adopted for the sympathetic inflammation in the other eye, a marked improvement had manifested itself in the injured one.

On examining it, I observed the following remarkable appearance. The cornea was entire, and perfectly transparent. No trace of the iris, however, was visible, not even a lacerated shred, insomuch that, at first sight, I assumed that it had been altogether torn away. The posterior media appeared perfectly transparent, for a light placed in front of the patient was reflected from the fundus. No sclerotic or corneal laceration was visible, but close to the superior and internal junction of the sclerotic and cornea, lay a yellowish, cheesy-looking body, covered by the unbroken conjunctiva, and lying between it and the sclerotic. This I recognised at once as the lens which had been forced through a laceration in the sclerotic, and now lay between the conjunctiva and sclerotic, and, as I judged, covering the wound through which it had escaped. Having diagnosed so formidable an injury as sclerotic rupture, complete evulsion of the lens and total traumatic mydriasis, I had little hopes that the retinal sensitiveness had survived the injury. As much for curiosity as any other reason, I placed the patient before the ophthalmoscope, and was surprised to find the retina in a very excellent condition of preservation, considering the condition of the eye. There were one or two small ecchymoses, and a slight detachment of the retina, close to the ora serrata, but the general surface of the fundus might almost be said to be natural.

It at once struck me that the loss of sight, which I ascertained, on inquiry, was rather an apparent blurring of all images, than any loss of the natural degree of illumination, might be largely dependent on the removal of the natural accommodatory appliances, and after further investigation, I satisfied myself that the loss of vision was not greater than might be supposed to arise from the admission of lateral rays through the ciliary opening, and from the absence of the lens.

In order to satisfy myself how much of it was due to the loss of the iris, I blackened a piece of card, and having cut a hole the size of a normal pupil in it, directed the patient to go out and walk up and down the street, and look through the opening. In a moment he returned, and announced to me a very remarkable improvement with, however, the same want of definition of the images as before. I therefore determined to endeavour to remedy the loss of the iris and lens by mechanical means, and I directed the patient to return home, and to come to town again in ten days. I instructed Mr. Spencer of Grafton-street to make for me the spectacles which I produce for the inspection of the meeting. I adopted for the framework one of the ordinary wire-gauge goggles, with the object of cutting off all lateral rays of light, the nose piece being made reversible, so as to enable the left eye of the spectacles to be turned over to the right side when required. In each eye I had inserted a thin brass diaphragm blackened and perforated with a hole, a twelfth of an inch in diameter. In front of these diaphragms I had placed a double convex lens of 2½ inches focal length, and in the other a similar lens of 4½ inches, these being the powers which I have generally found most useful in cataract cases. It will be understood that the object of this arrangement was to enable the spectacles to be used as well for near as distant objects, by simply reversing the glasses. The arrangement proved satisfactory beyond my most sanguine expectations, for, on the return of my patient, and his putting on the glasses, he was enabled to read without difficulty the smallest of Jægers' test types, which I produce for inspection. On reversing the glasses, and going into the street, also, the result of the adaptation for distant objects appeared equally successful, for the patient was able to read the name on the corner of the street at a distance of about thirty yards. In a couple of days I saw him again, and he expressed himself as having nothing to desire either in the extent of his sight, or the comfort of the spectacles.

Subconjunctival dislocation of the lens is a condition mentioned in most of the standard Ophthalmic treatises as peculiarly rare, and it will be easily understood how seldom an injury sufficient to effect a rupture of the sclerotic coat can occur without including the conjunctiva in the lesion. It is evident that the injury must be inflicted with a blunt object, and that the loose attachment of the conjunctiva enables it to yield before a blow, which may rupture the more rigid sclerotic. Cases are even recorded where the lens has become fixed half way out of the wound, a still more remarkable condition. Plate 19 of "Sichel's Iconographie Ophthalmologique," which lies on the table, contains two very beautiful illustrations of the condition—one of which, figure 4, almost exactly represents the position and appearance of the lens in my case. In both of those which he narrates, M. Sichel removed the opaque lens. It would have been easy for me to do so, but as the patient was indisposed to submit to operation—there being only one very delicate eye between him and total blindness—and as for nearly a year the lens had remained *in situ* without causing the least annoyance, I allowed the patient to return home with a warning, that if it became troublesome, it must be removed at once.

As I have said, the lens in my case was perfectly opaque, and of the cheesy consistency, this was only to be expected, as the capsule appeared to be ruptured, and as a year had passed since the accident; but Mr. White Cooper mentions a case in which the lens, having been dislocated beneath the conjunctiva, remained for a considerable time transparent.

The injury to the retina appears also to be usually less considerable than might be anticipated, for in each of M. Sichel's cases, considerable improvement, though of no means as much as was experienced by my patient, occurred from the use of cataract glasses. I presume, therefore, that the most hopeful cases are those in which the intra-ocular hæmorrhage is slight, and the absorption of the blood, which, in this case, followed on the administration of the mercury for the inflammation of the other eye, almost complete.

Mr. Henry Power, in his lately published work, figures and relates a case in which for nearly three weeks, the dislocated lens was overlooked, and on extraction at the end of that time, was transparent. He also says that, in these cases, sight is usually irrecoverably lost.

Dr. MACNAMARA wished to be informed of Dr. Frank Porter's

reasons for abstaining from the use of mercury? He knew that in the present day there was a crusade against mercury. He joined in the crusade against the abuse of it, but he thought these were cases in which it could be given with advantage.

Dr. FRANK PORTER had several reasons for not giving mercury. In the first place, the patient would not go into hospital, but remained at his out-door work, and he did not consider it prudent to put him under the influence of mercury, when he was exposed to the inclemency of the weather. Moreover, the man had a scrofulous appearance, and scrofula was in his family. At the time he saw him, the acute inflammation had subsided, and therefore he resolved to try iodide of potassium, and some other remedies.

PURPURA MALIGNA COMPLICATED WITH CEREBRO-SPINAL ARACHNITIS.

By J. H. BENSON.

Mr. President—The case which I have the honour to lay before the Society this evening, will prove, I hope, of some interest. It is a case of that fearful disease which began to show itself in Dublin early in the spring of 1866, and was variously named "black death," "purpura maligna," "febris nigra," "cerebro-spinal fever," and by some made synonymous with "cerebro-spinal arachnitis."

There seems, still, but little known as to its exact nature, and, therefore, any case of the kind where the symptoms and pathological appearances can be recorded and compared cannot fail to be of interest, as adding a mite to our scanty stock of knowledge of its nature.

T. K., æt. 21, a labouring man, came to Dublin from the county Carlow, on Saturday, Nov. 4th, 1867, and was admitted the same day into the wards of the City of Dublin Hospital.

He was suffering from strumous ophthalmia, and was placed under the care of Dr. Jacob.

At the date of his admission he complained of nothing but the affection of the eyes, and seemed perfectly healthy in every other respect. All next day, Sunday, he remained in the apparent enjoyment of good health and excellent spirits. He was cheerful and amusing in his manner, and partook heartily of dinner and supper. However, soon after he retired to bed, he was seized with a rigor, and vomited twice; but passed the rest of the night without attracting any attention on the part of the nurse, or his fellow-patients, from whom I have collected the latter facts. Next morning he was seen to lie apparently in a heavy sleep, out of which he could not be roused. In the middle of the same day, Monday, I saw him in consultation with my friend and colleague, Dr. Jacob, whose patient he had been. The man was then lying on his side; his respiration was of a heavy sibilant character, its frequency being 41 in the minute. His eyes were half open. The pupils were natural, and obeyed the stimulus of light. When addressed loudly he either took no notice of it or else moaned, or muttered something inarticulately; and when an examination of the body was being made he resisted, drew up the clothes hurriedly, or threw himself about in bed, changing posture repeatedly from side to side, and muttering unintelligibly all the time.

The pulse was weak, frequent, and extremely irregular. When counted, results were obtained in consecutive minutes varying from 90 to 125. The respirations, as I said, were about 41 in the minute, but besides their frequency and sibilant character, there was another remarkable feature connected with them. Very similar to what is observed in many cases of fatty degeneration of the heart or diaphragm, the respirations rose and fell in force, and depth, and frequency—at one moment being slow and noiseless, and after a few seconds becoming gradually more and more noisy, deep, and rapid, and again falling by degrees till they became almost natural. The interval of time between two successive maxima or minima of intensity varied slightly, but was about one minute.

With this rise and fall of the respiration there was a strange coincidence of fluctuation in the pulse. When the respiration was at its minimum the pulse was comparatively slow and steady, scarcely remitting, not weaker than at other moments, and easily counted. But as the respiration rose to its maximum the pulse became so rapid, intermitting, uncertain and fluttering, that it required an effort to count it, and the actual number of beats became more a matter of conjecture than of certainty.

My young friend, Mr. Haddon, a most intelligent pupil, remarked to me the strong general resemblance which the restlessness and other symptoms of the disease, in this man, bore to the case of a friend of his who had died some months previously from the so-called "febris nigra," and on examining the body we discovered numerous small, dark, irregular-shaped, purple spots, varying in diameter from one to five, or six lines, and not having very sharply defined edges. They were not affected by pressure. Some were very slightly elevated, others not at all so. They were found chiefly on the thighs, legs, buttocks, and back. The abdomen and chest were perfectly free from morbid discolouration. A few small spots occurred on the face, and a minute one on the right conjunctiva of the lower lid near the sclerotic. The skin was dry, but not hot. The patient had passed the usual quantity of urine, which was of a healthy appearance. The bowels had been moved naturally on the previous day.

The head was ordered to be shaved and blistered with Tichborne's vesicating collodion. All attempts to administer either medicines or aliments by the mouth failed, as the patient spit them, or rather blew them out of the mouth through the lips. Enemata were, therefore, administered every second hour, consisting of brandy, sulphuric æther, Hoffman's æther, and beef-tea made from Liebig's extract of beef.

In the evening the patient was found still restless, and tossing from side to side, requiring the constant attendance of the nurse at his bed-side to prevent him throwing himself out of bed. The respiration was more natural; no hissing. The ascending and descending character of the respiration was less marked. The patient was capable of being roused to a slightly conscious state when loudly addressed. He put out the tongue when desired, and it was seen to be dry in the centre with a red tip and edges; it was not tremulous. He would answer questions in the monosyllables, "yes" or "no," and would then talk or mutter about something totally irrelevant to the subject. In this way he denied the existence of any pain at one moment, and at the next affirmed that it was present, sometimes in the head, and sometimes in the chest, abdomen, or elsewhere. He would take stimulants by the mouth, and was somewhat obedient. The pulse was not so irregular, was less fluctuating, and was stronger than in the morning.

Tuesday.—The restlessness was unabated. Sordes was collected on the lips and teeth. The tongue was dry in the centre, and red at the tip and edges as before. The pulse was stronger and more regular; frequency about 112. The dark purple spots had not increased either in size or in depth of colour.

It was ordered that he should continue his stimulants and beef-tea, and that he should have a larger portion of the scalp vesicated.

In the evening the pulse was down to 90, and was full, strong, and almost deserving the description of being regular. There was less sordes about the mouth. The tongue was not so dry.

The patient answered questions better and more intelligibly than at any previous period of the illness, but was still delirious and very restless.

The temperature in the axilla was found to be 99°·9.

Wednesday.—The patient passed a restless night. He was still delirious, and throwing himself about in bed. The pulse was found to have risen; it was then 102, irregular, remittant, but moderately full; the tongue was more dry than on the previous evening; he was still unconscious. The temperature in the axilla could not be ascertained owing to his extreme restlessness, but in the rectum it was 100°·2, since the previous evening a number of papular spots had appeared scattered over the body, but especially on the legs and the lower part of the back. They partly disappeared on pressure. The original dark eruption had not changed in character, except that it began to assume a slightly reddish tinge.

He was ordered bark, chlorate of potash, hydrochloric acid, spirits of nitric æther, and sulphuric æther in a mixture, and to continue the use of the brandy and beef-tea.

In the evening he complained of some stiffness in the neck, but denied the presence of pain or uneasiness either there or elsewhere. There was no retraction of the head, nor any tenderness felt along the spine. The pulse was 114, and was steady, regular, and moderately full. By this time there was a total absence of the ascending and descending character of the respiration. The patient was still extremely restless, though not so much so as hitherto. The tongue was again very dry but not quivering. The first sound of the heart was strong and natural. The papulæ, which were discovered in the morning, had not increased in number. The original purpuric patches had not further altered. The temperature in the

rectum was 101°·2. He was ordered a purgative enema, and to go on with the stimulants and beef-tea.

Thursday.—The patient spent the previous night in the usual restless way; pulse 108, and remarkably strong, full, and regular; tongue cleaner than on the previous night. The man denied the existence of pain anywhere, yet he was observed to wince slightly when an attempt was made to bend the head forward so as to approximate the chin to the chest. The temperature was 101°·4.

He had been going on apparently as well as usual throughout the day, but in the evening he rapidly sank, and died almost without warning.

In making the post-mortem examination, I secured the valuable assistance of my friend and colleague, Dr. Hewitt, who kindly took the following notes:—

Autopsy, twelve hours after death.—Rigor mortis fully established; the hands, portions of the anterior surface of the lower extremities, the backs of the legs and thighs, the loins and back are of a mottled plum-colour, which disappears on pressure, but those parts of the body which come in contact with the wooden bier on which it lay, are perfectly colourless.

The spots observed before death do not disappear on pressure and are not perceptibly raised, they are still visible on the legs, thighs, buttocks, and loins, and they vary much in size and shape.

The face and neck are also, in parts, of the same purple black colour, but these do not present the same ecchymotic appearance observed in other cases.

The pupil of the left eye is dilated, that of the right is contracted.

On making an incision through the scalp, form ear to ear, a considerable quantity of dark fluid blood oozed from the vessels, and a similar oozing took place from the vessels of the bone when the scalp was torn away.

The cerebral sinuses are not much distended, but the inner surface of the dura mater is much congested.

The entire surface of the cerebrum is very red, and in the grooves corresponding to the sulci, there is a small quantity of greenish-yellow lymph underneath the arachnoid; a much larger quantity exists at the base of the brain in the fissures of Sylvius, in the circle of Willis, and, in less quantity, over the pons varolii and the middle lobes of the cerebrum. The exudation is soft and almost purulent in appearance, and when viewed by the microscope is seen to consist almost entirely of pus cells.

There was a considerable amount of bloody serum, which welled up from the base of the brain when the tentorium was divided.

The blood in the vertebral veins was dark and fluid, and did readily coagulate, and the coagulum when formed was readily broken down. Some bubbles of gas were seen in one or two of the cerebral veins, and the same appearance was observed in the internal mammary vein.

The medulla oblongata was congested. The cervical portion of the cord was removed, and although considerable congestion was evident there was not a trace of either lymph or pus present. But when the entire column was laid bare, it was found that there was an abundant sub-arachnoid exudation extending throughout the dorsal and lumbar regions as far as to the extremity of the conda equina.

This exudation proved to be pus. No unequivocal lymph was found. The substance of the cord was not softened nor otherwise visibly altered.

The brain substance was a little softened; there were a great many bloody points visible in the cerebrum; the ventricles contained some bloody serum which, when examined under the microscope, was found to contain both blood and pus cells; in the posterior corner of the left lateral ventricle there was a very small quantity of pus on the free surface of its lining membrane.

The corpora striata were found to contain several vessels loaded with dark fluid blood.

In the Thorax.—Some old adhesions were found tying down the right lung, which was considerably congested, and presented on its posterior surface a great many dark purplish-black spots, which, on section, were found to extend very slightly into the substance of the lung, and were very similar in appearance to the cutaneous stains. The left lung was much more congested, the entire of the lower lobe was dark and solid, refusing to crepitate on pressure; this was completely limited by the fissure, the upper lobe being only slightly congested.

The internal surface of the pericardium was perfectly smooth, but in some parts there appeared an ecchymotic staining under the serous layer. It contained a small quantity of yellow purulent fluid. The heart was small, but otherwise healthy.

The liver was greatly enlarged, and very soft and congested; and the gall-bladder was almost full of dark green viscid bile, which afforded the usual "play of colours" when treated with nitric acid; but which gave no result with Pettenkoffer's test.

The internal surface of the gall-bladder presented the normal reticulated structure, and was stained of a dark green.

The stomach contained a quantity of viscid bloody mucous, and its internal surface was intensely congested, the veins being greatly enlarged and turgid with fluid blood, and the capillaries much injected.

The peritoneum was healthy.

[On account of the pressure on our columns, the remaining portion of this Report is unavoidably held over until our next.]

Correspondence.

MEDICAL INVENTIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Have you ever heard of, or known, the results of water spray in the treatment of burns or scalds, in the first and second degree?

Have you ever heard or known of a musico-chordal stethoscope for accurately detecting the sounds of the heart, arteries, or lungs, in health or disease? Also, early pregnancy?

Submit these questions to the Medical Profession through your honest journal, as I have reason to think my ideas are original, and if they are, shall claim them before the medical public, by facts and statements, proving their value.—Yours truly,

A MEDICAL INVENTOR,
AND MEMBER OF COUNCIL OF THE ROYAL INVENTORS' INSTITUTE OF LONDON.

London, 18th Jan., 1868.

MIDDLE-CLASS LUNATIC ASYLUMS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your number of yesterday's date, I find an article upon the want of Middle-class Lunatic Asylums, where suitable accommodation could be had at a moderate charge. I beg to inform you that this accommodation has been, for some time past, provided by the Magistrates of the County of Dorset, at the Forston Asylum, near Dorchester, under the management of Mr. J. G. Symes, and which has given general satisfaction. —I am, Sir, your obedient servant,

T. J. EAMES BROWN, M.R.C.S. Eng., & L.S.A.

Dorchester, 16th January, 1868.

QUACK PAMPHLETS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I enclose for your inspection, a copy of a most abominable quack pamphlet, which has on two occasions during the present and past months, been extensively distributed among the young people of both sexes in this town.

The merest glance at its disgusting contents, will convince you that it is demoralizing in the extreme, and that the scoundrel who penned it has committed a serious crime against society and morals.

A country gentleman, of independent means, and the father of a large family, told me to-day, that a copy of the pamphlet in question had found its way into his house, and he expressed his surprise, in very indignant terms, that such fellows as the author should be allowed to corrupt the youth of the country without let or hindrance.

Is there no means by which the public can be protected from this obscene quack?—Your obedient servant,

JACQUES.

Clones, Jan. 14, 1868.

CORONER FOR THE WESTERN DIVISION OF MIDDLESEX.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As soon as I found out that Dr. Hardwicke was also a candidate for the above, I felt it to be my duty to retire from the contest, knowing he could appeal with the greatest confidence to the way in which he has for years performed the duties of Coroner (as the deputy to the largest division of the county.) Trusting the profession may be united upon this

matter, and only send *one good man* to the poll, who can and has a right to command success, I am, sir, your obedient servant, HOLT DUNN.

Gleanings.

MEDICAL PATENTS.—A Letter on the Patenting of Inventions in connection with Medicine. By John Chapman, M.D., M.R.C.P. Reprinted from the MEDICAL PRESS AND CIRCULAR. (Trubner.)—In this pamphlet the well-known advocate of the ice-bag as a therapeutical agent reprints a letter which was published in the MEDICAL PRESS AND CIRCULAR, but rejected by the *British Medical Journal*. Dr. Chapman brings two charges against the profession—one of completely ignoring his theory by declining to discuss it; and the other of attempting to ignore him by excluding him from its societies. In point of fact, Dr. Chapman is at war with the faculty on a point of etiquette, or, as those who consider the question a grave one would say, a point of ethics. It is a recognised principle among medical men that the patenting of inventions relating to the treatment of disease is objectionable, and tends to lower the dignity of the profession. Dr. Chapman has invented and patented a peculiar form of bag for the application of ice to the spine, and for this offence an effort is made to taboo him. To go into the matter fully would involve a greater space than we can afford, for it would require a discussion of the whole principles of the patent protection. But, admitting that patents are justifiable, we see no rational grounds on which the profession can object to the steps Dr. Chapman has taken. Of course, the traditions of the faculty, the spirit of conservatism, and so forth, all tend to oppose the patenting of medical instruments; but beyond these motives of prejudice we see no logical objection to the practice. Medical men urge that if a physician patents an instrument, he has the power of unduly promoting the sale and use of his invention. This is, however, an assumption, and one which involves (*a*) that the practitioner is unconscientious, and (*b*) that his efforts in an unfair direction would escape detection. Till this assumption can be shown to be true and to be of general application, we hold that Dr. Chapman's view is unimpeachable. The analogy which Dr. Chapman induces between the patenting of an apparatus and the registration of a copyright is more apparent than sound, especially in its application to the point at issue. The dishonest practitioner may advise his patients to employ an instrument of his invention, but he can hardly do much to promote the sale of a book. It certainly appears hard and unfair that the fruit of a man's brains should fall into the hands of a trader—as in the case of Dr. Richardson's *un*patented spray-producer—and that the original inventor should be rewarded with barren honour alone. It seems to us, therefore, that Dr. Chapman's arguments are in the main perfectly reasonable; and we cannot but think that the medical journals have displayed a feeling quite out of accordance with the true spirit of the press in refusing insertion to Dr. Chapman's letter.—*London Review.*

HEALTH OF SCOTLAND.—In the month of November last the deaths of 2049 were registered in the eight principal towns of Scotland—Glasgow, Edinburgh, Leith, Greenock, Dundee, Aberdeen, Paisley, and Perth. Allowing for increase of population, this number was 293 under the average of the month for the last ten years, so that the month of November was unusually healthy. Of the 2049 deaths, 959, or 46 per cent., were those of children under five years of age. In Aberdeen, 26 per cent. of the deaths were under five years of age, while in Greenock, Glasgow, and Paisley the proportional numbers were 50, 51, and 55 respectively. The epidemic and contagious class of diseases proved fatal to 457 persons, constituting 22 per cent of the mortality. This proportion was scarcely exceeded in any of the towns. Typhus was the most fatal epidemic; it caused 131 deaths, or 6·3 per cent. of the whole mortality. In Aberdeen 9·5 per cent. of the deaths were from that cause. Next to typhus, scarlatina was the most fatal epidemic; it caused 108 deaths, or 5·3 per cent. of the mortality. Whooping-cough caused 69 deaths, and diphtheria 21. The deaths from affections of the respiratory organs amounted to 460, besides 208 from consumption. There were 54 deaths from violent causes—three were suicides. One death was caused by intemperance. One male and three females had reached the age of 90 years and upwards, the oldest of whom was a tailor, aged 95. The births registered in November, in the eight towns, were 3150, a larger number than in November of any of the previous ten years. The marriages were 899, being about 22 above the average of the last ten years. The month was chiefly distinguished, in a meteorological point of view, for dryness and warmth, with the wind generally from the W. N. W. The mean temperature of these towns 42·2, was 1·3 deg. above the average. At Dundee 0·40 in. of rain fell; at Greenock 1·84in. fell.

Medical News.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—The following gentlemen obtained the Licences in Medicine and Midwifery, in October, November, and December last:—

Thomas Edward Carroll, Dundalk; Edward Joseph Curran, Enniskymon; William Henry Dodd, Killorglin; Henry Eames, 8, Upper Fitzwilliam-street; Frederick Fitzgibbon, Rosscarbery; Peter Thomas Frazer, Donaghmore; Albert Halahan L'Estrange, 4, Belgrave-road; Francis Adolphus L'Estrange, 4, Belgrave-road; Richard Macken, 5, North Earl-street; Matthew Henry Molloy, Dromore, County Tyrone; Hussey De Burgh Twiss Riordan, Youghal; Robert Henry Robinson, Parsonstown; Hugh Brady White, Killmoylan; Thomas John Wilkin, Lisbellaw; Evan Williams, 1, Arundel-place, London.

The following obtained the Licence to practise Medicine:—

Richard Vincent M'Carthy, 4, Upper Ely-place; William Daniel Moore, M.D.Dub., 40, Fitzwilliam-square; Daniel Thornton, Kinnetty; Thomas Torney, M.D.St. And., 8, Blackhall-street.

The following obtained the Licence in Midwifery:—

John Brown, L.K.Q.C.P., 22, North Frederick-street; John Francis Fitzpatrick, M.D.Queen's Univ., Mallow; William Marcus M'Dermott, L.K.Q.C.P., Foxford; Thomas Purcell, L.K.Q.C.P., 71, Harcourt-street; George Vesey Wood, M.D.Queen's Univ., 1, Vesey-terrace, Rathgar.

MEDICAL CHARITIES.—The funds of the following institutions have just been augmented under the will of Mr. Jabez Legg, of Stratford, Essex, who has bequeathed £100 each to the West Ham, Stratford, and South Essex Dispensaries. Mrs. Elizabeth Bond, of Devonshire-place, has bequeathed to the Middlesex Hospital £100; the Newman-street Lying-in Institution, £50; the Charing-cross Hospital, £50; the Consumption Hospital, Brompton, £100; and the St. Marylebone General Dispensary, £50. Mrs. Maria Otley, of Little Gonerby, has bequeathed to St. George's Hospital, £70; to the Lincoln Hospital, £50; the Lincoln Lunatic Asylum, £50; and a like amount to the Hospital for Diseases of the Skin. Each of these benevolent individuals has left liberal bequests to other institutions not strictly medical.—*Med. Times and Gaz.*

THE Examiners for the Radcliffe Travelling Fellowship, give notice that the next examination will commence on Monday, February 3, at 10 A.M., in the Museum. Candidates are requested to forward notice immediately to Dr. Acland of their intention to present themselves. H. W. Acland, D.M.; G. Rolleston, D.M.; and B. C. Brodie, M.A., examiners.

NOTICES TO CORRESPONDENTS.

Contributions should be *legibly* written, only on one side of the paper and *must be* in the hands of the Printer eight days previous to their appearing.

When proofs are forwarded it is of the utmost importance that they should be corrected and returned without delay.

OBSTETRICUS will find the new elastic band made by Messrs. Pope and Plante, of Waterloo-place, a great improvement upon the ordinary abdominal belt. Its advantages are, the lightness of the material, and the facility by which it can be enlarged, when needful, without unfastening.

Dr. CHESHIRE, Birmingham, would oblige by forwarding a second copy.

SIGNOR ANACLERIO.—The copies have been sent to the parties named.

Dr. G.—We cannot well re-open the subject, but will keep your note before us for a time.

F. E. M.—Not by any means an easy case for diagnosis.

Communications with enclosures received from Dr. Davies, Pershore; R. Tatham, Esq., Burton-in-Horisdale; Dr. J. W. Clements, Lindley; Dr. Lloyd Roberts, Manchester; Dr. Day, Stafford; Dr. Von Tunzelmann, Rumson; Dr. Hitchins, Brailes; J. Cooksey, Esq., Malvern; Dr. Sellars, Gurnnslake; Dr. Carey, Taunton; Mr. Bryden, Affcuhne; Mr. Leeson, Sandown; Mr. Langdale, Bedford-square, W.C.; W. West, Esq., Great Malvern; Dr. Horner, Chester; J. Sloane, Esq., Forest Row; Dr. Midwood, Manchester; D. Davids, Esq., Cowes; Dr. Smith, Ferbane; Dr. Sterling, Thomastown; Dr. Blackwell, Ballas; Dr. Crely, Aylesburg; Dr. Neilson, Killala; Dr. Crean, Wexford; Dr. Diamond, Rarharkin; Dr. Swan, Abbeyleix; Dr. Mac Cormac, Belfast; Dr. Calahan, Galway; Dr. Darley, Duleek; Dr. Mahon, Westport; Dr. Nolan, Wicklow; Dr. Kincaid, Tuam; Dr. Mulvany, Canada West; Dr. Foster, Birmingham.

THE CANTOR LECTURES AT THE SOCIETY OF ARTS.

Dr. LETHEBY'S FIRST LECTURE ON FOOD.

VARIETIES OF FOOD—THEIR CHEMICAL COMPOSITION AND NUTRITIVE VALUE.

The economy of food, in its fullest signification, is a matter of national importance; for the political influence of a nation is as much dependant upon the muscular strength of the people as upon their intelligence and commercial industry; and this strength is wholly referable to a right use and proper distribution of food.

We perceive this, not merely in the calamities of actual want, as in the fevers of famine, but also in the less prominent, but equally significant decline of health in times of partial distress, when the vigour and energy of the poorer part of the population are so reduced as to lay them open to disease. In fact, the experience of our public hospitals too often elicits the fact that the wasted power of the patient has been the advent of incurable disease. Nor is this all; for, as Mr. Simon observes—"Long before insufficiency of diet is a matter of hygienic concern; long before the physiologist would think of counting the grains of nitrogen and carbon which intervene between life and starvation, the household will have been utterly destitute of material comfort; clothing and fuel will have been scantier than food; against inclemencies of weather there will have been no adequate protection; dwelling-space will have been stinted to the degree in which over-crowding produces or increases disease; the home will be where shelter can be cheapest bought, where sanitary appliances are least considered, and where cleanliness is almost impossible. And all this distress falls heaviest upon those who are least able to bear it—the mother and her children; for the father, to be able to work, even lightly, must eat, and thus the others are the largest sufferers. Bad, however, as the immediate consequences are, they are nothing in comparison to the remote—the sickly race that comes of want.

In examining, therefore, this question of the economy of food, we must not only look at the nutritive value of different articles of diet, but we must also consider how food can be best distributed and utilized.

To-day we will examine the principal varieties of foods, and ascertain their peculiar qualities and dietetical values. For this purpose it will be necessary to have some standard for comparison, and this is avowedly a difficult matter; for if we compare foods according to the proportions of their principal constituents—viz., albuminous matters, starchy, saccharine, and saline—we shall find that the relative quantities vary to such a degree as to make the comparison almost useless; and if we fix our attention on one of these constituents—the nitrogenous, for example—and make it the exponent of nutritive value, we get into the difficulty of either overloading the equivalent with a large amount of carbonaceous material, or of having it deficient therein. If, for instance, we desire to know the quantities of different foods which would furnish the 1200 grains of nitrogenous matter required by a man in his daily diet, we should find that the following are the proportions:—

TABLE No. 1.

PROPORTIONS OF DIFFERENT FOODS REQUIRED TO YIELD 1200 GRAINS OF NITROGENOUS MATTER:—

	Grains.	Pounds.
Skim-cheese	2,681	0·4
Lean meat	6,217	0·9
White fish	6,630	1·0
Fat meat	9,231	1·3
Fat bacon	13,636	2·0
Bread	14,815	2·1
Rice	19,048	2·7
New-milk	29,268	4·2
Potatoes	57,143	8·2
Parsnips or turnips	100,000	14·3
Beer or porter	1,200,000	171·4

In this manner tables have been constructed of the nutritive values of food, and I show you one of them.

TABLE No. 2.

NUTRITIVE EQUIVALENTS—CALCULATED ACCORDING TO THE AMOUNTS OF NITROGEN IN THE DRY SUBSTANCES; HUMAN MILK BEING 100:—

Vegetable.		Animal.	
Rice	81	Human milk	100
Potatoes	84	Cows' milk	237
Maize	100	Yolk of Egg	305
Rye	106	Oysters	305

Vegetable.		Animal.	
Radish	106	Cheese	331
Wheat	119	Eel	434
Barley	125	Mussel	528
Oats	138	Ox-liver	570
White bread	142	Pigeon	756
Black bread	166	Mutton	773
Peas	239	Salmon	776
Lentils	276	Lamb	833
Haricots	283	White of egg	845
Beans	320	Lobster	859
		Skate	859
		Veal	873
		Beef	880
		Pork	893
		Turbot	898
		Ham	910
		Herring	914

I hardly need say that comparisons of this description are of little practical value, for they furnish no indication of the defective labour required to utilize the products; besides which we are far from being assured, at the present time, that the nitrogenous elements of our foods are the most important.

In framing, therefore, a table of alimentary equivalents regard must be paid to all the constituents, as I have endeavoured to do in Table No. 3, wherein I have shown the percentage composition of different foods, the total properties per cent. of nitrogenous and carbonaceous matter, and the proportions of the latter to one of the former; but here again the actual value of the several carbonaceous compounds is very different; for, although the fattening and respiratory powers of starch, gum, sugar, and pectin, may be nearly the same, yet the power of fat is about 2·5 times as great as that of sugar; and this must be considered, irrespective of other functions of fat, in estimating the value of carbonaceous food.

Table No. 3.—Nutritive Values of Foods.

	Water.	Albumen, &c.	Starch, &c.	Sugar.	Fat.	Salts.	Total Per Cent.		Carbonaceous to one Nitrogenous.
							Nitrogenous.	Carbonaceous.	
Bread	37	8·1	47·4	3·6	1·6	2·3	8·1	52·6	6·5

Another method of determining the values of food is by estimating the proportions of nitrogen and carbon in them, and comparing them with the proportions required in a standard diet.

Judging from the minimum quantities of food which an ordinary individual is capable of living on, without suffering in health, it would seem that about 4100 grains of carbon, and 190 grains of nitrogen are required in his daily diet. These proportions have been determined from a large number of observations, as by those of Dr. Lyon Playfair, in his inquiries into the dietaries of hospitals, prisons, and workhouses, and by those of Dr. Edward Smith, in his examination of the amounts of food which the Lancashire operatives were capable of living on during the cotton famine, and also by his inquiries into the dietaries of indoor labourers. The proportions which Dr. Smith gives as a famine or barely sustaining diet, are the following:—

	Carbon (grains).	Nitrogen (grains).
Adult Woman ...	3900 ...	180
Adult Man ...	4300 ...	200
Average Adult ...	4100 ...	190

These proportions are contained in 2lbs., and in 2lbs. 3oz. of bread; and they closely accord with another set of facts,

derived from an examination of the amounts of carbon and nitrogen exhaled and secreted from the body during health and idleness.

Taking these numbers, therefore, as the exponents of the nutritive values of food, we are able to construct the following table :—

TABLE No. 4.—NUTRITIVE VALUES OF FOOD.

	Grains per lb.		Value per Pound.	Grains for 1d.		Weekly Cost of Famine Diet for	
	Carbon.	Nitrogen.		Carbon.	Nitrogen.	Carbon.	Nitrogen.
			d.			d.	d.
Split Peas	2730	255	1	2730	255	10·5	5·2
Indian Meal	2800	123	1	2800	123	10·2	10·8
Barley Meal	2730	70	1	2730	70	10·5	19·0
Rye Meal	2660	88	1¼	2128	70	13·5	19·0
Seconds Flour	2660	120	1½	1773	80	16·2	16·6

Beer and Porter	315	1	1	315	1	91·1	1330·0

And now we may proceed to examine in detail the general properties, and the nutritive qualities of different foods.

Primarily all our foods are derived from the vegetable kingdom, for no animal has the physiological power of associating mineral elements, and forming them into food. What we may yet do by means of chemical agencies in the laboratory is another question ; but within our own bodies there is no faculty for such conversion. As I shall hereafter explain to you, our functions are of an opposite kind. We are destructive creatures, not constructive. It is our province to pull down what the vegetable has built up ; to let loose the affinities which the plant has brought into bondage, and to restore to inanimate nature the matter and cosmical force which the growing plant had taken from her.

Foremost, therefore, of our foods are those which come at once from the vegetable kingdom ; and of these the *cerials* are the most important, as wheat, barley, oats, rye, maize, or Indian corn, rice, millet or Durra, and Guinea corn.

Wheat.—Different species of this grain are cultivated, but the most common in this country is *Triticum vulgare*, of which there is a summer and winter variety.

The grain varies a good deal in composition according to season, climate, and soil ; but, as a rule, the wheat of Southern climates, and warm seasons, is richer in gluten, and of harder texture than that of colder times. They are then called stronger grains, although the latter, from their being softer and kinder, give a larger proportion of flour. Some of the hardest varieties of wheat, as *rivets*, are used to strengthen the flour of new grain, which is always unmanageable, and to improve that of bad seasons and of damaged quality.

The structure of the grain is like that of all the cereals : there is an outer siliceous and woody covering which is altogether valuless as food ; then there is a layer of rich nitrogenous matter, containing a digestive body called *cerealine*, and within that is the flour, which forms the great bulk of the seed.

When ground whole, it forms *brown meal*, which is rarely used in England at the present time, although it was the common food of our forefathers, and even now is much employed in Westphalia, to make the dark-coloured bread called *pumper-nickel*. It contains from 5 to 12 per cent. of indigestible matter, in the form of bran, the removal of which, according to Liebig, is only a refinement of luxury.

The practice at the present time is to bolt or sift the ground meal through sieves, or silks, of different degrees of fineness, and thus to remove the coarser bran. The products have different names in different places, and have also different values ; but generally a hundred pounds of wheat will yield from 78 to 80 parts of good serviceable flour. The other products are about 2 parts of *specks*, or *tails*, or *tippings* ; from 2 to 3 parts of *sharps* ; about 3 of *fine pollard* ; from 3·5 to 6 of *coarse pollard* ; and from 4 to 10 of *bran*. The relative wholesale values of these are about as follows :—

	Lbs. per Bushel.		Price per Bushel. s.	d.		Price per 20lbs. s.	d.
Fine flour	56	—	10	0	—	3	7
Second do.	56	—	7	9	—	2	9
Sharps	26	—	2	0	—	1	6
Fine Pollards	18	—	1	0	—	1	1
Coarse do.	14	—	0	10	—	1	2
Bran	12	—	0	9	—	1	3

Seconds flour is practically the best for domestic use; and of this there should be at least 80 per cent. from the grain. Attempts have often been made to increase the produce; for as the bran contains a good deal of nitrogenous matter, and is, moreover, rich in fat and saline substances, it has been thought wasteful to remove it: but the experimental researches of Poggiale, the learned professor at Val-de-Grace, have shown that at least 50 per cent. of bran is perfectly indigestible, and may be passed successively through the bodies of four or five animals without undergoing change. It, moreover, acts as an irritant; and, by hurrying the food through the alimentary canal, is very likely to cause waste. Those who labour hard, as railway navigators, invariably choose the whitest bread for food, believing that it is not only more digestible, but is stronger, and will enable them to do more work. Without doubt, however, there is room for improvement in the treatment of flour, and in the complete utilization of its several constituents. M. Mège Mouries has invented a process whereby the outer skin only of the wheat may be removed, and from 86 to 88 per cent. of flour realized. The process was examined in 1857, and reported very favourably of by Dumas, Pelouze, Payen, Peligot, and Chevruel, but I am not aware that it has come into use.

M. Mège Mouries also directed attention to the fact that the bran contains a portion of very soluble nitrogenous matter, *cerealine*, which is of the nature of diastase, and has the property of dissolving starch. This, no doubt, might be utilized by treating bran with warm water, and then using the water in the manufacture of bread.

The nutritive value of wheat is shown in Tables No. 3 and No. 4; and, although the average amount of gluten is there set down at about 11 per cent., it ranges from 8 to 15 per cent.—the largest quantity being found in the wheaten flour of India, Egypt, South America, and the South of Europe.

It appears, too, that the quantity of gluten, as represented by nitrogen, increases with the coarseness of the flour, and so, also, does the amount of mineral matter.

TABLE No. 5.

PERCENTAGE AMOUNTS OF NITROGEN AND MINERAL MATTER IN THE DIFFERENT PRODUCTS OF THE MILL:—

	Nitrogen.		Mineral Matter.
Fine Flour	1·70	—	0·71
Tails	1·86	—	0·99
Fine Sharps	2·21	—	1·89
Coarse Sharps	2·58	—	3·80
Fine Pollard	2·44	—	5·50
Coarse Pollard	2·42	—	6·50
Bran	2·39	—	7·00
Average in whole grain	1·82	—	1·62

The starch and sugar amount to about 70·5 per cent. and the fat to 1·7; so that the carbonaceous is to the nitrogenous as 6·7 to 1, which is a good proportion. Other facts relating to its nutritive value are shown in table No. 4.

The tests for a good flour are its sweetness and freedom from acidity or musty flavour; and its nutritive value, as far as gluten is concerned, is estimated by the process of Beccaria, who discovered gluten in wheat more than a century ago. A given weight of flour (say 500 grains) is made into a stiff dough, and is carefully washed by tender manipulation under a small stream of water. The gluten remains, and when baked it expands into a clean-looking ball, which should weigh, when thoroughly dried, about 54 grains.

Of all the preparations of flour, *bread* is the most important. I shall hereafter describe the process of making it, but I may here remark that it should not contain more than from 36 to 38 per cent. of water, and the other constituents, excepting salt, should be the same as of good flour.

In practice, 100 lbs. of flour will make from 133 to 137 lbs. of bread, a good average being 134; so that a sack of flour of 286 lbs. should yield 95 four-pound loaves. The art of the baker, however, is to increase this quantity, and he does it by hardening the gluten through the agency of a little alum, or by means of a gummy mess of boiled rice, three or four pounds of which will, when boiled for two or three hours in as many gallons of water, make a sack of flour yield 100 four-pound loaves. But the bread is dropsical, and gets soft and sodden at the base where it stands. A good loaf should have the following character:—

Kindness of structure—that is, not chaffy, or flaky, or crummy, or sodden; and

Sweetness to the palate and to the smell.

Wheaten bread is best eaten on the day after it is baked, for new bread is difficult of mastication, and still more difficult of digestion, because of its gummy nature. When it becomes stale it does not really get much dryer, but it undergoes a molecular change, which may be restored by heating the bread in a closed vessel to a temperature of 212°.

Wheaten bread is preferred to all other varieties of bread because of its sweetness, and because it may be eaten alone. The nutritive constituents of it are in the same proportion as in wheat—namely, as 1 to 6·5, and a little more than two pounds of bread will supply the requirements of the system; although, as I shall hereafter explain, it cannot be used alone without loss of health and strength.

Barley-meal is the chief food of a large number of people in the North of Europe and in the South of England, where the labourer is partly paid his wages in meal or grain. It is also used in Wales and Scotland, especially in winter-time, when wheaten bread is dear; and to some extent in Ireland. It is employed by about ninety per cent. of the outdoor labouring population of England. At the time of Charles I. (in 1626), according to M'Culloch, it was the usual food of the ordinary part of people, and as late as the middle of the last century hardly any wheat was used in the northern counties of England. In Cumberland the principal families used only a small quantity about Christmas-time; and the crust of the everlasting goose-pie, which adorned the table of every country family, was invariably made of barley-meal.

The grain is almost always ground whole, and the farina has much resemblance to wheaten flour; but the amount of gluten is very different, in fact, the nitrogenous matter, which amounts to about six per cent., is chiefly in the form of albumen, hence, the bread is heavy and compact, for albumen will not vesiculate or sponge like gluten. The common way of making it into bread, is by mixing it with an equal proportion of wheaten flour, and sometimes it is mixed with oatmeal and rye-meal, and baked into cakes. But the best way of using it is in the form of thick gruel or stirabout, which is made by stirring the meal into boiling water.

Pearl Barley and *Scotch Barley* are the grain deprived of its husk, and rounded by attrition. The former is more carefully prepared than the latter, but both are used to give consistence to broth.

The nutritive value of barley meal is somewhat inferior to that of wheaten flour, but as the meal is cheaper than flour, it is more economical to use it, in fact, it is almost the cheapest article of diet, as may be seen by reference to Table No. 4.

Oatmeal and rye-bread were once the chief diet of the servants of the wealthy, and even now the former is used by 90 per cent. of the agricultural labourers of England, and by a still larger proportion of the Scotch. The grain is very rich in gluten and fat, and it contains a good quantity of sugar and starch, the microscopic form of which is remarkable. The Scotch meal is always preferable to the

English, on account of its higher nutritive power. It is prepared by grinding the kiln-dried grains, previously deprived of their skins. The Scotch grind it rather coarsely as compared with the practice in England.

Oatmeal is not nearly so white as wheaten flour, and its taste is peculiar, being at first sweet and then rough and bitter. Like barley-meal it cannot be vesiculated into bread but it makes good cakes, and these may be either leavened, as is the custom in Yorkshire, or unleavened as in Scotland.

The common method of cooking it, however, is by stirring it into boiling water until it has the consistence of hasty-pudding, and in this manner *porridge* is made ; but if it be afterwards boiled for a short time it makes Scotch *brose*. In Ireland it is mixed with Indian meal, and then stirred into boiling water, thus making the mixture called *stirabout*.

The decorticated grain constitutes *grits* or *groats*, and when these are crushed or bruised they go by the name of *Emden groats*. The sole use of them is for making gruel, a drink that seems to have been a favourite with our forefathers ; for in the *London Gazette*, for Friday, August 13, 1695, there is an advertisement to the effect that water-gruel was always ready at the Marine Coffee-house, in Birchin-lane, Cornhill, every morning from 6 to 11 o'clock, and, it added, that as much as from four to five gallons of it were consumed there daily.

The husks of the grains are sold in Scotland under the name of *seeds*, and these, when steeped in water for a few days until they become a little sour like stale brewer's grains, and then squeezed out, produce a liquid, which, when boiled down to the consistence of gruel, makes the food called *flummery*, or *sowans* in Scotland, and *sucan* in South Wales. If it be boiled still more, until it becomes as thick as jelly, it forms *budrum*, or *brwchan*, as it is named in Wales. Oatmeal is, no doubt, rather hard of digestion, and causes irritation of the bowels. There is a notion also that it produces heat and irritation of the skin ; and formerly, when sufficient care was not taken to remove the husk from the grain before it was ground, it was not an uncommon thing to find calculi or concretions of phosphate of lime, mixed with the silky bristles of the grain, in the alimentary canal. Somewhat similar concretions are found at the present time in the bowels of horses that feed too freely on bran or grains. The nutritive value of oatmeal is shown in Tables No. 3 and No. 4, and it will be noticed that although it is weight for weight more nutritive than wheaten flour, yet, considering its price, it is not so economical.

Rye meal is the chief food of northern nations, and was once a common article of diet with ourselves. It forms the dark coloured, and sour tasting bread of the North of Europe. In this country it is rarely eaten alone, but is mixed with about twice its bulk of wheaten-flour, forming what in many places is called *maslin*, and is then made into bread. The nutritive power of rye-meal is a little less than that of flour, and the proportion of the nitrogenous to the carbonaceous constituents is as 1 to 9·4.

(To be continued.)

LECTURES ON VENEREAL DISEASES

DELIVERED IN

DR. STEEVENS' HOSPITAL.

LECTURE I.

By ROBERT McDONNELL, M.D., F.R.S.,

ONE OF THE SURGEONS TO STEEVENS' HOSPITAL.

GENTLEMEN,—The range of your studies offers few subjects at once so interesting and so perplexing as that of venereal diseases. The commonness of the complaints, the formidable aspects they not unfrequently assume, invite your attention ; while you must be struck by the difference of opinion which exists, and has long existed, even among the greatest writers who have treated of this subject. The teaching of the leading syphilographers of France, Germany, and England, are far from being in harmony with each other. This work, which I hold in my hand, the recently published report of a committee appointed to inquire into the pathology and treatment of the venereal diseases, strikingly attests what difference of opinion still exists among British surgeons upon this subject. You yourselves are well aware how varied is the doctrine inculcated in different hospitals, nay, even in the same wards, you often find that the surgeon you follow to-day holds views different from him you may follow to-morrow.

In this hospital you have excellent opportunities afforded you for studying these complaints ; for in the year 1820, when the Lock Hospital of this city was closed against the reception of male cases, at the request of the government, provision was made in this hospital for the treatment of male venereal patients, and this practice is still continued.

It is only of late years that it can be said that venereal complaints have been studied with anything like scientific accuracy. It was a saying of our forefathers *si in dubio suspice venerem*, and what Hunter wrote nearly 100 years ago is indeed applicable to to-day. "There is even at this day hardly any disease that the practitioner is puzzled about, but the venereal comes immediately into his mind;" and this tendency to regard every obscure symptom as in some way connected with venereal disease has been one of the greatest obstacles to its elucidation.

But, as regards syphilis, as in the working out of many other scientific problems, the chief difficulties which have obscured the field of investigation, have been the pre-conceived notions which possessed the mind of the investigator. For, in the first place, maladies which we now-a-days regard as several distinct diseases were formerly confounded with each other, because they were all supposed to have one and the same origin—to spring from one and the same poison. In the second place, it was an idea handed down from master to pupil for centuries, that unless stayed in its progress by the most active treatment, syphilis was a complaint which would go on slowly but surely from bad to worse. Beginning like a snowball rolling down the mountain side, it would end in the avalanche sweeping all before it. Commencing, in fact, in a little sore not bigger than a pea, that it would by degrees attack the glands, the throat, the skin, later the bones and vital organs, and, finally, "having retreated to its last citadel, the head, and, like a skilful general, broken down the bridge behind it," it would bring down the few hairs which still remained with sorrow to the grave. The natural result of this belief regarding the progress of syphilis was that it was attacked in the most furious manner by the most violent remedies, and the monster-malady was so defaced and disfigured as to be made a thousand fold more hideous than nature had made it. Under these circumstances it was difficult to recognise the true features of the complaint. It were as though an astronomer should attempt to map out the spots upon the sun when the sky was overcast by clouds, or an artist to take a likeness from a distorted image seen reflected in a silver dish cover. Thanks, however, to the researches of later times, many of the clouds have been cleared away, although much remains for you yet to do. One group of investigators has placed in their true light the several distinct diseases which until lately were confounded together ; while another, by studying the progress of syphilis when allowed to run on in its own course, not interfered with by the action of so-called specifics, has given us a correct image of the monster in his natural state. It is true Caliban is an unsightly beast at the best, yet he appears now-a-days to be a less formidable enemy to contend with than when it was more the fashion to goad him into fury with weapons, which, at the best, only for a time, subdued him, and often only enraged without overcoming him.

In collecting the evidence upon which our judgment

is to be formed upon this subject, we must be guided—first, by the opinions of persons who have given close attention and study to the subject; secondly, by facts, observations, and experience recorded by truthful observers; and thirdly, by the facts and cases which have occurred under our own eyes. We shall first examine the opinions of some of the most distinguished writers of the present day, and in doing so, I shall draw my evidence, for the most part, from the report already alluded to, from the recently published work of Lancereaux, and from the works of Lee, Virchow, and Diday. The illustrious Hunter, as you are, no doubt, aware, was led by observation and experiment to the erroneous conclusion that gonorrhœa and chancre are the effects of the same poison. Later, Mr. Abernethy fell into the equally great error of believing that diseases which got well without the use of mercury were not syphilitic.

As some confusion has arisen among writers on this subject from the nomenclature of these diseases, I should propose that hereafter clinical teachers in this country should adopt the names used in the report of the Venereal Committee. According to this report, venereal disease presents itself in two forms, gonorrhœa, and sores or ulcers. Of venereal sores or ulcers there are two species, one of which effects the constitution, while the other does not. They are termed syphilitic and simple.

It is a pity that the term "small-pox" is pre-occupied. If we could call the syphilitic sore the "great," and the simple venereal sore the "small" pox, we should at least have good Saxon words to indicate the formidable proportions of the one disease as compared with the other. Indeed, they might be very well designated on this principle—"the big and the little pox," were it not that, in truth, we have too many names already.

We find, then, in actual existence three venereal diseases: 1st, gonorrhœa; 2nd, the simple venereal sore; and 3rd, the syphilitic venereal sore.

Of gonorrhœa I speak merely to say, that the opinion of Hunter is now, I believe, universally abandoned. Even before his time, in 1767, Balfour maintained that gonorrhœa and syphilis were distinct maladies, and this view was afterwards advocated by Ellis, Duncan, Bell, and Bosquillon.

It remained, however, for Hernandez, Cockburn, M'Gregor, Hennen, and Guthrie, to establish this proposition which has been verified, and, in short, clearly demonstrated as a fact by the experiments of Ricord and Rollet. The co-existence of urethral chancre with the gonorrhœa, or the fact of an urethral chancre being mistaken for gonorrhœa, was, no doubt, one of the chief causes which rendered it difficult to establish, with absolute certainty, a fact which appears to us so very simple.

The simple venereal sore which, by various writers, has been described as false syphilis, local syphilis, soft chancre, suppurating chancre, non-infecting chancre, chancroid, chancrelle, is now regarded as a local disease, incapable of infecting the constitution. Its influence, in fact, never extends beyond the inguinal glands. It is, however, eminently contagious, producing sores like itself. It is the most common form of venereal sore. Very often several such sores occur upon the same subject. The pus which gives rise to it retains its influence for a long time. Ricord has inoculated successfully with pus preserved for 17 days. It begins in a pustule; its edges are perpendicular, as if punched out. For a time it tends to spread superficially. It secretes pus freely, and, generally speaking, is as soft as the parts around it—so much so—that if the eyes were shut, one could rarely discover by the touch the situation of the sore. But descriptions of it are unnecessary. You must learn its appearance from seeing and examining it, and of this you have opportunities every day.

The syphilitic sore—which is also known as true syphilis, the Hunterian chancre, indurated chancre, the non-suppurating chancre, the infecting chancre—is the disease which is the forerunner of constitutional syphilis. From the names which have been given to it, you may infer some of its most marked characteristics—that it was recognized and described by Hunter; that it has often hardness of the base; that it does not suppurate easily; that it infects the system; that it alone is really deserving of the name of syphilis. The hardness around its base is its most marked characteristic. Any one familiar with this symptom could diagnose it blindfold. Although its most marked symptom, yet it is not always present.

Fortunately for mankind, this (the big pox) is less common than the simple venereal sore.

According to the report of the Venereal Committee, the proportion is about four simple to one syphilitic.

Puche found in 10,000 chancres—
8,045 simple chancres.
1,955 syphilitic.

Fournier has seen in 341 chancres—
215 simple chancres.
126 syphilitic.

It appears to be agreed, therefore, on all hands that the simple ulcer is much the commoner disease; for these statistics harmonize very well with those of our own naval and military authorities.

The syphilitic sore is said to occur under three forms. Firstly, that of a dry papule; secondly, the chancrous erosion; and thirdly, the hard chancre. In the first two forms the characteristic hardness is wanting, and this is no doubt one of the causes why the infecting form of the disease was so long confounded with the local one.

You may ask, are we able in practice to distinguish with certainty the one of these diseases from the other? Can we, when we see a patient for the first time suffering from a venereal sore, say whether that sore will or will not be the forerunner of constitutional syphilis? In answering this question, I say that it is not possible to pronounce with certainty whether it will or will not be followed by constitutional symptoms; but, on the other hand, you may often make the diagnosis with the highest degree of probability. If, for instance, you find the characteristic hardness which forms, if not an invariable, at least a most important symptom of the syphilitic sore, you may say to your patient that the chances are about a hundred to one that he will some time hence suffer from secondary syphilis, and this opinion you may form with almost absolute certainty if you find that the hard sore is accompanied by a hard gland which rolls like a marble beneath the skin in the groin. If, on the other hand, you find several sores free from hardness, suppurating freely, you may give your patient good hopes that no constitutional disease is in store for him, and you may be more hopeful still if you find in the groin a bubo, which, instead of being hard and indolent, runs rapidly forward to suppuration.

Let me advise you, however, in such a case, not to give your patient any positive assurance that secondary disease will not follow. Tell him that he has a disease with the characters of the simple venereal sore; that you have every reason *to hope* that his constitution may escape scot free. But no positive assurance—*crede experto*. Do not be rash, or you may rue it. Be hopeful—nothing more. We cannot make the diagnosis with certainty.

If, on the other hand, circumstances enable your patient to fix positively the date of his impure contact; and if a fortnight or three weeks have elapsed between that time and the day when he perceived the sore, even although there is no hardness, you will regard the affection as probably syphilitic, and almost certainly so if you have a hard gland in the groin.

Of the three forms in which constitutional syphilis has been observed to commence—1st. The dry papule appears to be the rarest, as it is likewise the most likely to escape observation. 2nd. The chancrous or chancriform erosion (which was, no doubt, the patchy excoriation of Carmichael, and the superficial primary syphilis of Wallace, the parchment chancre of Ricord, the venerola vulgaris of Evans, the condylomatous affection of Rinecker, the superficial erosion of Langlebert,) is, accord-

ing to Bassereau and Diday, the most frequent form in which primary infecting syphilis manifests itself. 3rd. The indurated chancre, which, according to Lee, is the commonest form of infecting syphilis, is the least likely to escape observation, and certainly that in which the ultimate consequences of the disease may be foretold with the greatest certainty.

Many persons seem to think that the questions—

A.—Has the syphilitic sore a period of incubation?

B.—Is it true that the syphilitic sore cannot be inoculated on the subject that already has one?

C.—Can a syphilitic sore be "aborted" (and the progress of the disease cut short) by being cut out, or burned out with escharotics?

are questions only interesting in a theoretic point of view. They are, however, eminently practical. On the answers to these questions our opinion must be formed, our reasoning must be based.

For, if it be true that the syphilitic sore has a period of incubation—(*i.e.*, a period of some weeks elapsing between the day of infection and that on which the sore appears) if it, from that time, is not reinoculable on another part of the patient, if it is not abortible, then it follows, as clearly as possible, that in such case the *so-called primary lesion* is not really the primary lesion. The initial lesion must be that which takes place *on the day of infection*, and at the time when the sore becomes apparent the constitution is already engaged; from that time the enemy is no longer threatening our shores, he has crept in unknown to us and made good his footing; he already holds the avenues leading through the frame, and the chancre is, as it were, the standard already floating on the citadel.

Let us, then, examine carefully into these questions. The simple sore appears early, within three or four days after intercourse. The syphilitic sore comes on at a later period from the probable time of infection; has it what is called a period of incubation?

A.—QUESTION OF INCUBATION.

The question whether there be any fixed and definite period between the exposure to contagion, and the appearance of the sore, is one of great scientific interest, and I believe one of great practical importance also. Although we have some important evidence upon the subject, the question may be said, however, to be one which is still *sub judice*. It appears to be of much practical importance, because if it be established that a period of some weeks must elapse between the exposure to infection and the appearance of the disease, it becomes probable that when the disease first becomes apparent the system is already infected. Analogy would lead us to suppose that such a period of incubation does exist, as we know it does in small-pox, measles, and such complaints, and it must follow as a corollary, assuming a term of incubation really to exist, that when the disease makes its appearance in the tangible form of chancre it is already past the hope of remedy by an abortive treatment. Thanks to inoculations practised upon hitherto healthy individuals, the incubation of syphilis which was for a long time denied by a celebrated school, has had some light thrown upon it in these latter days. However unjustifiable such inoculations may be, we may, at least, profit by the facts which have been thus developed. The weight of evidence brought before the Venereal Committee preponderates in favour of the view, that there is no definite period of incubation either for the simple or the syphilitic sore. Continental writers, however, give some important facts upon this subject, and the experiments alluded to go far to prove that a fixed period between infection and the appearance of the disease does exist. The same view is also countenanced by the information derived from the unfortunate occurrence of syphilis in the children vaccinated with impure virus at Rivalta. From the experimental inoculations made by Wallace, of Dublin; Vidal; Waller, of Prague; Rinecker, of Wurtzburg; Rollet, Gibert, and Pellizzari, it would appear that a period of twenty-eight days on an average elapses between the time of inoculation and the appearance of the chancre. From these experiments it results that the slight wound made at the time of inoculation soon cicatrises, as though it were nothing more than a simple puncture. The cure does not, however, last long; for soon there appears a lesion, which is the first appearance of the syphilitic disturbance, eighteen days being the shortest, and thirty-five days the longest time which has elapsed in any one of these experiments between the inoculation, and the manifestation of the disease. Diday, from his observation in the cases of twenty-nine patients, in which he obtained his information as accurately as one ever can from such cases, arrives at the conclusion that fourteen days is the mean period elapsing between infection and the appearance of the disease.

Dr. Viennois has been led by his investigations, to conclude that the vaccine disease and syphilis may be inoculated at the sametime. The cow-pox then appears first, having a shorter period of incubation, and, after a time, the chancre makes its appearance upon the inoculated part, and is followed by secondary symptoms. In the unfortunate occurrence already alluded to, and carefully investigated by Dr. Pacchiotti, Professor of Surgery at Turin, and entitled by him "Syphilis transmitted by means of vaccination at Rivalta," the period of incubation for the syphilitic poison appears to have averaged about 20 days. The medical men appointed to report upon this remarkable outbreak say, that the syphilitic symptoms showed themselves at periods varying from ten days to two months. In the remarkable experiment made in May, 1867, by John Hunter, in which he is generally believed to have made the inoculation upon himself, he says four months after the inoculation, the chancre on the prepuce broke out again. You see, therefore, that although there is evidence that with reference to the syphilitic sore, a period of incubation actually occurs, yet the question is one of those which requires further precise observations before the time at least can be distinctly fixed. I have myself met with one case in which circumstances fix the period with some precision. A man came from America in a sailing ship. He was six weeks at sea, and was in good health during this time. He was not exposed to contagion during the voyage. Upon arriving in Dublin he devoted one night to dissipation. Upon the following day he was taken by the police and thrown into the Mountjoy prison, under the Habeas Corpus Suspension Act. Four days afterwards I inspected him, and he drew my attention to an excoriation on the frenum. One week afterwards I again inspected him, and found this healed, simply with water dressing, and it was not until 20 days later, that is 31 days after the impure connection, that he came before me with a chancre behind the corona, already slightly indurated. Possibly this sore may have been in existence for some days, but he assured me, positively, that it could not have existed for more than four days, as he had washed himself thoroughly on the Sunday before, without seeing it. Two months later he had secondary syphilis, in the form of aroseolar eruption, although the sore had been freely burned with caustic on the first day that my attention was directed to it.

(To be continued.)

CLINICAL REMARKS ON DISEASES OF THE ANKLE AND FOOT.

By HOLMES COOTE,

LECTURER ON SURGERY, AND SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

I HAVE under treatment two cases of chronic disease of the ankle-joint. Both the patients are somewhat delicate young women, who, in spite of an early warning of pain, have been obliged to exert themselves to obtain a living. One is a laundress, the other a domestic servant. The symptoms have in both been much the same—namely, unendurable pain and swelling of the joint after standing or

walking. In the latter case the disease was most advanced, inasmuch as abscesses had formed from time to time, and the probe passes down to diseased bone.

So long had this unsatisfactory condition of the joints lasted, and so unable were the patients to follow any remunerative employment, that they came into the hospital, willing to submit to amputation of the affected limbs. But, although still to some extent uncertain as to the ultimate result, I saw nothing incurable in the parts, if kept for some months in a state of complete rest; and I therefore, after bringing the joints into a quiet state, had them encased in an immovable bandage, and supplied the patients with lightly-constructed wooden legs, which enable them to walk about and follow some avocation on the bended knee.

The courage of the second patient however soon failed, and she insisted on being relieved of that which was a constant source of suffering. I accordingly amputated the leg at the lower third, January 19. On examination of the diseased parts we found that there had been long-standing disease of the astragalus, the articulating surfaces of which were entirely denuded of cartilage. Anchylosis had taken place between its upper surface and the lower end of the tibia, while its under surface was connected to the calcaneo-scaphoid articulation by fibrous tissue, which became stretched and painful when the patient rested on the foot. Other bones of the tarsus were also diseased.

Under favourable circumstances, and with care, the diseased parts may again become firm and healthy, and the patients regain their use. I will know how long it takes for a diseased ankle again to become sound. Indeed the late Mr. Stanley assured me that he had never met with a case of bony anchylosis after such an event. He and I, however, came across one specimen taken some time afterwards from the dissecting-room, and I hear that there are a few specimens in the museums of other hospitals.

These two cases induce me to offer a few remarks on diseases of the ankle-joint, which seem often but lightly passed over, and of this the reason appears to be that they often owe their origin, and are closely associated in many forms, with changes in the relations of the bones, such as are familiar enough to those who have been engaged in the practice of orthopædic surgery.

In the first place, what is meant by the ankle-joint; is the term limited to the articulation of the upper surface of the astragalus with the lower extremities of the tibia and fibula? This may be correct in strictly anatomical language, but in studying the pathology of the ankle, we must regard not only the upper, but also the under surface of the astragalus, that key-stone to the arch of the foot, as it is called, we must bear in mind its relations with the upper surface of the os calcis, and especially with the calcaneo-scaphoid ligament which receives the rounded head of the astragalus as in a socket. So long as the arch of the foot is intact, a person can move about all day without fatigue; when the arch of the foot is sinking, the pain is progressive, and becomes almost insupportable. After it has completely sunk, the head of the astragalus comes to the ground; the bony surfaces have not just their proper apposition; the foot feels to the patient "too long;" he does not put the sole flat upon the ground, but shuffles along, resting on the inner border of the foot; the peronei muscles become tight and rigid, and, after a time, the tendo-achillis will not let the foot be raised beyond the right angle.

If in this state of parts, the patient, as is commonly the case, wears heavy boots, somewhat short and narrow at the toes, the whole foot passes into a state of deformity, in which all its symmetry and delicacy of movement is lost. Frequent attacks of inflammation supervene; the bones themselves become involved, and I have had on more than one occasion been obliged to amputate the foot to remove a useless and painful appendage.

It is scarcely necessary to remark that the astragalus is not made to rest on the ground, and to sustain the weight of the body. It may, under such circumstances, become inflamed, when it casts off its cartilaginous coverings. The specimen here presented, (Ser. 11, No. 4), illustrates this point. It is an "ankle-joint," but nearly the whole of the articular cartilages have been removed, the small portions which remain are thinned, and their connection with the bones is loosened. The bones are superficially ulcerated, and very vascular, even the posterior surface of the astragalus, by which it articulates with the os calcis, is similarly diseased.

In the astragalus, as in the upper and lower extremities of the tibia, and the lower extremity of the femur, parts which directly receive the weight of the body, and which, more than any others, are exposed to sudden and often violent shocks, we meet with the same proneness to disease. In the case of the ankle, the morbid conditions are various, but the sinking of the arch, called talipes valgus, is one of the most common, and is a real calamity, especially to persons of active habits. In the early stages of this disease, almost immediate relief may be afforded by the use of well-made broad-soled boots, with a small pad just under the arch. The plan is to keep the patient constantly in bed, day and night, for a week or more, until all pain has subsided, and the tendons have become relaxed; should any remain persistently tense, they may be divided subcutaneously with advantage. The arch of the foot should then be slowly pressed up with proper splints and after a time the use of the padded boots be allowed. Sometimes outside irons are wanted, with a strap over the ankle.

By such simple means the arch of the foot may be maintained, and one source of disease, and that a common one, permanently removed. A tall girl, of about 12 or 13, was lately sent under my care from some part of Kent. She was so flat-footed as to be unable to walk any distance whatever. The treatment above recommended was carried out, and she went back home in comparative comfort. From some cause or misapprehension, she threw aside her boots too soon, when the deformity quickly returned, and she had again to go through the same course of treatment, and with a successful result.

I do not assert that with the sinking of the arch of the foot, disease of the bones is by any means an invariable result. It is only one cause out of many others, and should be borne in mind, the more so as it is preventible, and relief is afforded on very easy terms. The ankle-joint is liable to affections of strumous, of gouty, or of rheumatic character, but these are generally easily recognised. At the same time, I must observe that incipient flat foot has often, in my experience, been mistaken for rheumatic inflammation, and the usual remedies been applied without effect.

In close association with talipes valgus is another affection of joints, namely, disease of the metatarso-phalangeal articulation of the great toe. A respectable young man, clerk, and much on his feet, has just left the hospital, where he has been staying some months, under my care, in consequence of a painful swelling over the ball of the great toe of two years' duration. The parts are thickened and intensely tender. If he attempts to walk, the pain becomes unbearable, and when I first saw him, he had his foot in a slipper, bound up in soft cloths. Now what was the history of this case. He had flat feet; the elongated foot had been pushed into thick boots, narrowed at the toes; the great toe had been pressed inwards, the ligaments stretched, and the tendons thrown from their proper line of action. Can it be wondered that disease of the joint supervened; and, in these cases, the perplexing question arises, are we justified in amputating the offending member. True, surgery says no; but the patient is often worn out by suffering and sick of want of employment. However, in this case, I set the toe straight, and after relieving him of pain, dismissed him with directions to return, should he feel any further inconvenience.

In investigating the causes of flat feet, the surgeon would, of course, examine the knees, to see that they did not "turn in," a point easily ascertained.

HOW FAR ARE RESIDENCES IN ELEVATED SITUATIONS TO BE RECOMMENDED TO PERSONS THREATENED WITH OR SUFFERING FROM PHTHISIS PULMONALIS.

By C. R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.,
PHYSICIAN TO THE NORTH LONDON HOSPITAL FOR CONSUMPTION.

MANY physicians seem to think that the keen air of hills or mountains is more injurious to phthisical patients, by exciting bronchitis, than beneficial in warding off future deposits of tubercle ; and, doubtless, there is much truth in this view, that persons in the last stage of consumption will often linger on in less pain by seeking a sheltered spot. But, on the whole, I am inclined to believe that the bracing air of mountains and hills gives a better chance, so long as the patients are well housed and fed, of recovery, than situations of lower levels.

About a year ago, Dr. Hermann Weber called attention to the advantages which phthisical patients often obtained from residence in situations far above the level of the sea. And it has been remarked that in Germany, whilst the disease is very common in the manufacturing towns, it is rarely met with among the mountains above the height of 3500 feet over the sea. Lombard in his work declares that phthisis entirely disappears at the height of 5000 feet over the sea. The disease appears to be rare among the Neilgherry Hills, according to Villemin, and in the Himalaya Mountains, 5000 feet over the sea, it is also very rare.

Phthisis is said to be almost unknown in the high plateaux of the Rocky Mountains, Cordillieras, and Andes, in North and South America. On the high plains of Mexico, the rarity of tuberculosis contrasts with its frequency on the sea coasts. "There are in the Cordillieras, according to Guilbert, towns of ten, twenty, and forty thousand persons, where phthisis is never met with ; and Nicol, in ten years' practice (says Villemin in his recent work on tuberculosis, p. 366), had not met with one case of phthisis in La Paz, a town of 40,000 inhabitants, seated at 3700 metres above the sea, in Bolivia." When the inhabitants of these towns, however, descend to the sea-coast, they then become phthisical.

Pleurises and pneumonias are, however, common at these high altitudes.

There is so much evidence contained in the above statements taken from the recent work of Villemin, in favour of spots far above the level of the sea, as residences for those who are anxious to avoid any hereditary predisposition to phthisis breaking out, that perhaps it may not be illogical to infer, that even when this sad disease has attacked the lungs, a residence in situations as far above the sea-level as possible might prove of service in checking fresh deposits of tubercles, and thus arresting the disease. If this be true, it would then appear to follow, that in any future hospitals or sanitaria for consumptive patients, we ought rather to look about for high situations, than do as at present is being done—*i.e.*, seek to construct them on the level of the sea, as is proposed to be done in the Isle of Wight at present. I was led to think of this subject first by the papers of Dr. Hermann Weber, and since then, at the North London Hospital for consumption situated at Hampstead, not very far from the top of the hill, I have had an opportunity of observing, that several of those patients who suffered from cavity of the lung, have recovered their appetite after a few days stay in that hospital ; and been much benefitted, even in December, by walking on the high terrace walk at the top of the hill. So long as patients have a warm house and a good fire to fly to when in-doors, it seems to me that the higher the residence over the level of the sea, the better chance have they of the arrest of the disease.

PROFESSOR WHEATSTONE.—It is understood to be the intention of Government to confer Knighthood on Professor Wheatstone, in consideration of his great scientific attainments and of his valuable inventions.—*Pall-Mall Gazette.*

Hospital Reports.

ST. GEORGE'S HOSPITAL.

A YEAR'S SURGICAL DISEASES.

A SHORT time ago we gave a brief account of the accidents admitted during the year into the wards of this hospital, and carefully tabulated by Mr. Ring, Surgical Registrar, in the last volume of the reports. We propose to complete this aperçu of the surgical practice at St. George's, by an account of the surgical diseases as distinguished from accidents, and shall again have to utilize to a large extent on Mr. King's labours. To diffuse a knowledge of a volume like the St. George's Hospital Reports throughout the profession, is the best use to which we can put it, and the best compliment we can pay to the writers.

We have already given a summary of all the cases of Pyæmia (MEDICAL PRESS AND CIRCULAR, January 8th), and may therefore pass them over on this occasion. Of other general diseases we include erysipelas, sloughing, gangrene, and tetanus : these we treat to day, leaving diseases of special organs to a future occasion.

Of general diseases, then, we find that forty-three cases of erysipelas are recorded, and of these thirty-two were cutaneous, and eleven phlegmonous. Taking the cases of cutaneous erysipelas first, out of thirty-two cases, twenty-five were admitted with the disease, and seven only contracted it in the wards. All the cases that originated in the house were traumatic. Of those admitted, thirteen cases were traumatic and twelve idiopathic. A foot was often affected from wearing a tight boot ; twice scalp-wounds were attacked ; twice wounds of the face, &c. One case of idiopathic erysipelas of the scalp and face in a young woman terminated in an attack of mania. The cases of phlegmonous erysipelas were all traumatic ; eight were suffering from the disease when admitted, and three contracted it in the house. Of these two were of the forearm after amputation of crushed fingers, and one followed an extensive scalp-wound; the case terminated fatally from pyæmia. The treatment consisted in purgation, followed by bark, or more frequently of the tincture of the muriate of iron in half-drachm doses, with good diet and stimulants, especially brandy. The application of poultices, warm Goulard lotion, and laudanum, or of a lotion composed of half an ounce of tincture of iron to a pint of water, and occasionally incisions in the phlegmonous erysipelas, comprised the local treatment.

Phagedæna has been as rife as ever in the wards, and has marred some of the most promising operations, and carried off, or reduced to an extreme state of exhaustion, patients almost well. It was very frequent in the Fitzwilliam and Oxford wards soon after the houses had been pulled down in Grosvenor-place ; and it would appear not improbable that the miasmata arising from the recently-opened drains contributed in no small extent to produce the disease.

Forty-six cases occurred ; of these, thirty originated in the wards, and the remaining sixteen were admitted suffering from the disease. Of the thirty cases, ten occurred in the Fitzwilliam ward and eleven in the Oxford, with three in the Grosvenor and five in the Winchester—two smaller wards opposite the Fitzwilliam and Oxford respectively ; whilst on the opposite, or women's side of the house, only one case occurred, and that was in the accident-ward. The diseases attacked seven wounds, nine ulcers, six compound fractures, five cases of necrosed bone, two stumps after amputation, and one case of excision of the knee. Six cases necessitated amputation, four of which died. The greater number of cases occurred in the months of January, August, September, and October, although a few occasionally took place in all the months, May excepted. Seven cases proved fatal. Of the cases that broke out in the house, the mean duration of the disease was twelve days ; the maximum being thirty-six and the minimum three days. Of those admitted, the mean duration was 7·8 days ;

but many of these applied for relief some days after the sloughing had set in.

The treatment pursued presented but little variation. Gradually increased doses of opium, with bark and stimulants, were found the most useful remedies. Brandy was given in almost every case, but wine was sometimes substituted. Various topical applications were made use of; *e. g.* sulphate of copper, with extract of opium: sulphite of soda, and potassio-tartrate of iron; but those found most effectual were carbolic acid, charcoal poultices, and the unguentum viride (P. H.)

One case of senile grangrene occurred in a woman aged seventy-two. A slough formed on the outer side of the right leg, which on separating left an indolent ulcer, which took nearly three months to heal. The disease originated in a slight bruise which had been received two months previously.

Only two cases of tetanus occurred in the year; one after a burn, and one after a smashed hand. The first was treated by extract of woorali, the twelfth of a grain, subcutaneously injected, but soon proved fatal. In the second, sulphate of atropine was made use of, and death did not occur until the twelfth day. It is so interesting that we add Mr. Ring's history of it:—"M. B., æt. 28, a labourer, was admitted under the care of Mr. Tatum, with a smashed hand; the index-finger and part of its metacarpal bone were removed. He was placed upon ordinary diet, with beef-tea and a pint of porter. For the first few days he did well. On the evening of the 30th Oct., eight days after his admission, he complained of feeling his jaws stiff, and shortly afterwards had a slight rigor. Next day his jaws were still more rigid, and in the afternoon they were firmly locked; at the same time he suffered from opisthotonos, and complained of pain in the epigastrium, extending through to the back; his face was congested, deglutition difficult and attended with spasm. Atropine 1-45th of a grain was injected subcutaneously at 4 P.M., and again at midnight. After the first injection, his pulse was 144, and the spasm was partially relieved, but he complained of thirst and the locked state of his jaws; there was slight risus sardonicus, and his wounds looked dusky. Ordered brandy six ounces daily.

November 1st.—He was very restless during the night, and once persisted in getting out of bed to make water, when owing to the opisthotonos, great difficulty was experienced in getting him back again. The trismus continues the same, but the risus has passed off, the face being less congested. Pupils somewhat dilated; bowels confined. Pulse 120, and weak; temperature in axilla 100·4 Fahr. At 11 A.M. and again at 3 P.M. 1-20th of a grain of atropine was subcutaneously injected; and he was ordered half a pint of beef-tea, with brandy, to be injected per rectum, every three hours.

2nd.—He is in much the same state, but the risus has returned, and he complains of pain in the back of the neck, where the muscles are very rigid. Pupils dilated. At 11 A.M. 1-20th of a grain of atropine was injected. Pulse 106, stronger; temperature 100·1; respirations per minute 28.

3rd.—Was very restless during the night, and is now delirious. The opisthotonos and trismus are much less marked, and the jaws can be separated half an inch. The injections per rectum are returned almost directly after their administration. The wound is looking more healthy, and is discharging more freely. At 10.30 A.M. 1-20th of a grain of atropine was injected. Pulse 112, fuller; temperature 100·5; respirations 28.

4th.—The trismus is about the same as yesterday; when the jaws are separated, the tip of the tongue can be seen, dry and coated. He passed a quieter night, and is in less pain. The opisthotonos is much less severe; but he has occasionally starting pain in the back and right side, and now complains of pain in the hypogastrium and loins; has less delirium, but the risus is well marked. The injections are now retained for some time. At 10 P.M. 1-15th of a grain of atropine was injected. Pulse 100, softer and fuller; temperature 100·4; respirations 26.

5th.—The symptoms have undergone no change. 10.45 A.M.—Atropine gr. 1-20th.

6th.—The jaws fall open between the paroxysms of trismus, which, with the opisthotonos, comes on in spasms. Pupils dilated. Has had slight epistaxis. At 10.50 A.M. 1-20th of a grain of atropine was injected. Pulse 120, thready and sharp; temperature 102·4; respirations 30. Ice in India-rubber bags to be applied to the spine and back of the head, and the injections of atropine to be discontinued.

On the 7th and 8th he remained in the same state, but gradually got weaker; he was covered with a profuse offensive perspiration, and was very restless. Pulse 120, very weak; temperature 101·2; respirations 28.

9th.—There is less perspiration; the lips and teeth are covered with sordes. Trismus more marked; the opisthotonos comes on in paroxysms, with pain in the epigastrium. The injections are retained for about an hour; the bowels are rather loose, the discharges being dark, liquid, and offensive—consisting, in fact, of fæcal matter mixed with the injections.

On the 10th there was no appreciable alteration, except the increasing exhaustion. Pulse 132, very feeble; temperature 102; respirations 36; but at 5 P.M. the spasms became much more violent, and again at 12 P.M. they increased in severity, greatly impeding respiration.

At 3 A.M. on the 11th, it being evident that the man would not be likely to survive should another spasm supervene, laryngo-tracheotomy was performed. He appeared much easier after the operation; but a severe spasm coming on soon after, he sank asphyxiated under its influence."

During the early part of 1867 a case of tetanus recovered after the subcutaneous injection of a solution of sulphate of atropine and bimeconate of morphia combined. It will be related in the next volume of reports of St. George's.

At the post-mortem of the above case after hardening in chromic acid, sections of different portions of the spinal cord were made, and were examined under the microscope. As far as could be ascertained, the entire cord was perfectly healthy. No abnormal appearance could be discovered.

Mr. Ring remarked that in this case four points are worthy of notice.

"1st. That the atropine subcutaneously injected relieved the spasms.

"2nd. That the ice-bags had no effect; but of this it may be said that the restlessness of the patient rendered it difficult, and at times impossible, to keep them in their proper position for any length of time, which might to some extent account for the negative result.

"3rd. That the patient died from spasm, but not of the glottis, as the entrance to the air-passages was quite patent from the introduction of the tracheotomy tube; but probably the fatal spasm was of the diaphragm, and other respiratory muscles. This, however, does not disprove the assertion of those who declare that tetanus usually proves fatal by spasm of the glottis, but only that in this instance the fatal result was not attributable to that cause. Spasm of the glottis would be sufficient to cause death, without any affection of the other respiratory muscles; and laryngotomy under such circumstances would obviate the danger of asphyxia from that cause, and give the patient a further chance of lasting through the violence of the disease, though the probability is that spasm of the respiratory muscles or exhaustion would ultimately induce a fatal issue.

"4th. The patient survived longer than is usual, acute tetanus generally proving fatal on the third or fourth day; this man lived rather more than twelve days after the occurrence of the first symptoms."

CHAIR OF ENGINEERING AT EDINBURGH.—The Government has accepted the offer, made through the Senatus Academicus of Sir David Baxter, to found a Chair of Engineering, provided that a supplementary vote, equivalent to the interest of his benefaction, were asked from Parliament.

Literature.

PERIODICALS.

THE Half-Yearly's first claim a word, and of these, by right of seniority, our old friend Braithwaite. Here is the 56th volume for the latter half of 1867, which reached us from Messrs. Simpkin's punctually on New Year's Day. It opens with an excellent synopsis of the most practical articles in the volume, arranged alphabetically. It has always been the character of *Braithwaite's Retrospect* to be practical, and this character is well maintained. Our own columns have been freely drawn upon by the able editors.

We have also received the 46th vol. of the *Half-Yearly Abstract of the Medical Sciences*, published by Messrs. Churchill. This, also, is a selection of the literature of the half-year. Its aim is perhaps a little less practical and more scientific than its elder brother, Our own pages have also contributed to this. Those doubtful about which to consult, can easily try both—for they are both very useful and convenient-sized books.

QUARTERLIES.—The last number of the *Westminster Review* will interest many of our readers. We shall omit reference to its political articles as out of our province, to call attention to a careful essay on "Physiological Psychology," founded on Dr. Maudsley's new work, which we have not yet seen, by the bye, but which, from what appears in the *Westminster*, must be well worth attentive reading. The writer of the essay in the *Review* is convinced that we may yet make progress in our knowledge of the mind, by approaching it from the side of the body, and points out many of the advances made by the physiologists. At the same time, he admits, with Professor Chandler, that in spite of all the aid physiology has rendered, "it still remains true that physiology is one thing, and mental philosophy another." We are gradually brought up by the writer to the two opposing views:—that mental action is the "final achievement of organization;" or that there is a distinct ego apart, the chief argument for which is an appeal to individual consciousness. No attempt is made beyond this, except a statement that it is possible to reject both opinions, contenting oneself with studying facts, and "leaving the final generalization to an undefined and illimitable future." We confess to a certain feeling of disappointment in this conclusion, which, as it were, stays at the threshold, when we found the article suddenly closing with "which of all these is the best course to pursue we do not care to take upon us to decide." Not that we intend to take upon ourselves the responsibility, although we should have been happy to accompany this writer a little further. We ought to mention that there is also in the *Westminster* of this quarter, a learned essay on the "Origin of Electricity," which we are inclined to attribute to the pen of a foreign *savan*, and which is worth reading by everyone interested in such subjects—and who, in our profession, is not? We wish the many who make of electricity a mere amusement, would master this account of its origin. It would be worth their while to get the last number of the *Westminster* on purpose to do so, but they would also find in that review plenty of other change for their money.

The *Journal of Cutaneous Medicine*—(No. 4)—holds its ground bravely. The editorial commentary is rather more extended and very pleasantly written. A correspondent writes on the necessity for Professorships of Dermatology in our medical school, and exposes some of the selfish outcry that has been raised against special institutions. The hollowness of this abuse of useful charities has already been pointed out in our columns, and will again and again, we doubt not, form the subject of animated discussion, in the profession. Among the reviews there is a very smart article on the new pharmacopœia, pointing out how utterly inadequate are its formulæ for the treatment of cutaneous diseases of every day occurrence. The original communications are by Mr. E. Wilson, Dr. Sisson, Assistant-Surgeon Nicholson, and Dr. Bartley. The foreign literature of the quarter is reviewed by Mr. J. L. Milton.

The *Journal of Mental Science* has again reached us, after an intermission or two from some accident. This number opens with observations on the phenomena of life and mind, laid before the British Association, for the advancement of science, at Dundee, last September, by Dr. Robert Dunn. Then follows a less interesting but not less important paper—an elaborate abstract of the state of lunacy in Great Britain and Ireland in 1866. We recommend those who cannot or will not peruse the blue books of the Commissioners in Lunacy to avail themselves of this digest, which is sufficient for most purposes. Dr. Mitchell contributes a paper on the care and treatment of the insane poor; Dr. Gibson clinical cases, illustrating the value of the thermometer as a means of diagnosis in diseases of the nervous system; and Dr. Bateman, a paper on aphasia. There is the usual summary of notes and news, relating to the special subject to which this journal is devoted.

The *Dublin Quarterly Journal of Mental Science* has regularly reached us; and invariably keeps up its brilliant and practical reputation. As we have reviewed particular numbers of it from time to time, we need not now specify any particulars as to the volumes for 1867.

MONTHLIES.—We may first name the *Glasgow Medical Journal* which reaches us punctually every month, and always contains some practical and interesting matter. The clinical record is a valuable feature of this journal, as might well be expected, from the renown of the Glasgow hospitals, medical schools, and teachers. The proceedings of the Glasgow Medico-Chirurgical Association are naturally fully reported.

The *Edinburgh Medical Journal* has been regularly received. The January number for 1868 contains five original communications, eleven reviews, and much miscellaneous matter of interest.

Journal de Médecine Mentale.—This important and well-known French serial has been regularly received up to December, 1867. We need say nothing in commendation of the matter usually contained in it.

The *Journal de Médecine de Bordeaux* gives from month to month an excellent *resumé* of all the good work done in an active centre of medical learning and practice.

The *Journal de Médecine et de Chirurgie Pratiques* continues to hold its place as the most practical French medical periodical.

The *New York Medical Journal* and the *American Journal of the Medical Sciences* have both reached us regularly since we were mentioning periodicals last year. They both hold their places in the literary world, and require no recommendation from us. We have received an odd number or two of the *Pacific Medical and Surgical Journal*, and of the *Detroit Review of Medicine*. We hope they still survive, and enjoy all the support they deserve. From the numbers we have seen we formed a favourable opinion of them. A number of other American journals have reached us at irregular intervals. Even our exchanges do not come to hand with any degree of regularity—a sufficient indication that the communications between the two countries may be improved in many ways.

FORTNIGHTLY.—*Bulletin Général De Thérapeutique Medicale et Chirurgicale.*—We have received this famous periodical up to January 15, 1868. In that number is a paper on the employment of phosphorus in medicine, and, particularly, in progressive locomotor ataxy. Every number of this publication contains matter of peculiar interest to students of materia medica and therapeutics.

WEEKLY.—*Gazette Médicale De Paris.*—This has regularly come to hand up to the 18th of the present month; and it is fair to say that it maintains its interest and its usefulness to all who read the serials of French medical literature.

We have before us the *People's Magazine* of the Christian Knowledge Society from the commencement in January, 1867. Last year it appeared, as thousands of its readers are aware, weekly, and the volume for 1867 forms a very handsome and cheap present, which would not fail to be appreciated by the younger members of every family. Besides, tales by well-known authors, of which Holme Lee's *Mr. Wynyard's Ward* may serve as an example, we may state that there are many articles full of instructive and amusing information, while the magazine, being published by the Society for Promoting Christian Knowledge, requires no other guarantee that its tone is such that it may safely be introduced into every family. A NEW SERIES is commenced with this year. Henceforth it is only to be issued in monthly parts, price 6d., for 64 large pages, with a large coloured picture, a photo-lithograph, and numerous woodcuts. Certainly nothing cheaper can be expected.

The feature that has attracted our attention is that the January number (number 1 of new series) contains the first of some communications on "Physiology for Practical Use." This first paper is on the "Faculty of Hearing," and is evidently the production of one who is a complete master of his subject, as well as of literary skill. It is a model of the manner in which abstruse subjects may be popularized, and furnishes many useful hints without in any instance overstepping the bounds of propriety as to the information it is desirable to

impart to the public. If the succeeding articles on physiology should equal this, the *People's Magazine* will have accomplished something to give it a special claim on the support of the Profession. We should add that the new series is more clearly printed, on thicker paper, and is to be more profusely illustrated than ever. This is a very favourable opportunity of beginning to take in a magazine which will delight and instruct both young and old.

Though not exactly a periodical, we may here mention, as it appears in parts, the *Popular Educator*, which Messrs. Cassell are now re-issuing, and of which they have sent us the first part.

So, also, *Bible Animals*, edited by the Rev. J. G. Wood, and published by Messrs. Longmans. It will make a very handsome volume when completed.

We have also on our table a copy of the *Argosy*, which has passed into new hands, and is now edited by Mrs. H. Wood. We should have mentioned some other popular periodicals, but they reach us only occasionally, and cannot, therefore, expect to have space allotted to point out the articles we deem interesting to our readers.

WEDNESDAY, JANUARY 29, 1868.

THE SICK POOR.

BLUE-BOOKS, and for that matter, all official papers, are long in making their appearance. Whether the Poor-law Board have been roused by the revelations of the medical journals to urge their servants to more prompt action ; or, whether only in the due course of official tardiness, it is needless to inquire. A Parliamentary return has been issued, which shows that nearly two years ago the board entertained some misgivings respecting the condition of some of our English workhouses, and directed Dr. EDWARD SMITH to visit and report upon "the sufficiency of the existing arrangements for the care and treatment of the sick poor" in those establishments. The report, as now issued, bears evident marks of haste, and requires a considerable amount of attention to enable the reader to grasp its scope. The conclusions to which the facts elicited point, are not summed up in the manner common to these publications, and, in order to get at them, it is consequently necessary to diligently study the closely printed appendix of 125 pages. A careful analysis of these will, however, repay the trouble, although it may lead us to wish that the facts had been made public before this. Unless the whole of the results were to be condensed for general reading, it seems useless to have kept them back until they were rendered unnecessary by independent inquiry. Whatever may be the view adopted as to the propriety of such investigations being undertaken by, or permitted to be carried out by, individuals, it will now be generally admitted that an impartial inquiry was urgently needed, and that in conducting it, our contemporaries have acted with great prudence, and yet great firmness. The facts with which they startled their readers, have been fully borne out, and their suggestions will, we hope, be to a large extent adopted.

Thus, although, as we have said, no effort is made to show the results of the 48 workhouses submitted to special inspection, the reiteration in different cases, that *much improvement* is needed, cannot fail to have its influence on the reader. So also will statements that skin diseases are prolonged for weeks, that the sick wards are in a "disgusting" state ; that infectious cases are often not separated from others, that the beds are often too short, that the coverings are too old and too thin (we suppose, threadbare), and that many other facts clearly show that the workhouses are, on the whole, in a very unsatisfactory condition. What more is needed to justify the indignation of the press and the country ? What more need we ask to show that when we hinted that Farnham was but a specimen of many other places, we did not speak unadvisedly ? What more can the Poor-law Board ask than the testimony of its own officers, to rouse it from its state of torpor ? What more need Parliament wait for before asserting its authority, and throwing its protection over the diseased pauper ?

Englishmen have too often prided themselves on the institutions of their land, and boasted that they alone have a Poor-law. This assertion, however, will not bear investigation, if we look rather at things than at names. The State does not support the English hospitals; they are the monuments of private charity. But it is time the fact were admitted that Workhouse Infirmaries are in reality national hospitals. As such they are a disgrace to this rich and proud nation. They are inferior to the hospitals of many a fifth-rate municipality on the Continent, in which we have found comfort and cleanliness presiding, and a cheerfulness among the patients we have never encountered in English Workhouse Infirmaries. Why should this be ?

We are convinced that no good will come from all these enquiries until the principle shall be admitted that poverty and disease demand pity—not repression. The sick pauper is not a criminal, and yet his lot is too often far worse than that of the regular "jail-bird." Is it not a disgrace that the workhouse should be subjected to rigours, restrictions, petty tyrannies, and miseries innumerable, that have long been banished from the prisons ? Why, the workhouses are in fact prisons; for even in the country they seldom have gardens, and the inmates are restricted from going beyond the high walls that enclose their dreary court-yard and exercise grounds.

Dwellers in large cities set a high value on their little slip of garden, their squares, their parks, and other open spaces: they love to get away from the toil of work and the din of the noisy streets, and breathe for a time the sweet atmosphere of the fields and lanes: they believe that the fresh air invigorates them as well as cheers them, and they make great sacrifices for it. What, then, can they think of the lot of the old, infirm, and invalid poor, shut up in these dungeons provided by their tender guardians, and only sniffing the blessed air after it has crossed the cess-pool or the other abominations that reek around the "great house"? In the name of all that is just, give the sick pauper liberty to enjoy fresh air and as much sunshine as our climate affords.

We have another subject to remark upon, and one that more intimately concerns our Profession. Dr. E. SMITH reports as one result of his inspection that "it cannot be denied that the quantities of stimulants and the length of time during which they are ordered are sufficiently astonishing."

He seems to think that the Poor-law Board will have to take cognizance of the freedom with which poor-law surgeons prescribe alcohol. We commend this fact to Mr. SKEY, whose book was reviewed in our columns last week. It goes far to show that our critic was right in believing that Mr. SKEY's lessons had not been without effect. We know not whether Dr. SMITH has any serious intention of stigmatizing the practice of the poor-law surgeons as extravagant or reckless, but we do know that if he has he will find them able and ready to defend themselves. It may be freely conceded that there is much to be said on both sides in any controversy that may be raised upon the vague issue of prescribing stimuli in this or that disease; but we presume that in individual cases the responsibility must be left with the actual attendant; and in the case of the poor worn-out victims of disease and poverty who people our workhouses, the presumption will certainly, in most minds, be in favour of the value of alcohol as a remedy. Whatever the guardians of parishes may think, depend upon it the country will not grudge the sick poor the amount of wine or spirit that may be given as medicine.

Whether all the alcohol that is ordered finds its way to the patients, and if not, what becomes of it, may not be an unnecessary inquiry, and we think it more within the province of the Poor-law Board than a discussion of the therapeutical uses of stimulants.

PUBLIC HEALTH IN DUBLIN.

WE have fairly launched forth upon another year, and we would do well to observe, in respect to the state of the Public Health in Dublin, what prospect opens around us. It will be our duty to accept our position, and to manfully endeavour to improve it.

As sound commercial undertakings require constant supervision and due stock-taking, so it would ill become us, as Medical Journalists, to ignore the information afforded by the returns of the Registrar-General, and, in the present instance, we will confine our inquiries to those referring to Dublin.

Of zymotic diseases, it affords us satisfaction to observe that small-pox caused but 2 deaths last year in Dublin, instead of 25 in 1866, and 71 in 1865. Here is good encouragement for steady perseverance in the exertions of our professional brethren in the practice of vaccination, and of those who have influence to induce all classes to observe the provisions of the compulsory Vaccination Act.

Measles of a very fatal type has prevailed, especially in crowded and otherwise unwholesome localities, carrying off 405 persons in 1867, against 54 in the previous year. Surely these figures should arouse our city authorities to more activity in suppressing the great nuisance attending upon the feeding and housing of pigs in many of the most crowded parts of Dublin, and not infrequently under the same roof with human beings.[1] One medical friend of ours lately found a case of malignant purpuric fever that proved fatal, and, a little time after, one of dysentery and one of diarrhœa, under the same roof with several pigs, and in close proximity to a heap of most offensive manure, containing 40 or 50 loads; nor was this all, for in a large room, adjoining one occupied by one of the sick and other persons, large quantities of straw, taken from the manure, was being dried to serve as bedding for the swine. We wish, too, we could say that this was an exceptional case.

Scarlatina carried off 259, against 109 in 1866. Nor do these figures represent the many persons more or less injured for a long time, and, probably, in many instances for life, by the dregs of this treacherous disease.

Diphtheria, whooping-cough, fever, and dysentery, fell from an aggregate of 799 fatal cases in 1866, to one of 573 last year; while diarrhœa rose from 313 to 320, and of cholera but 38 deaths were registered last year. Other zymotic diseases fell from 345 to 312.

The severe weather in the earlier and in the latter months of 1867, accounts for the increase in mortality in diseases of the respiratory organs, and in those from constitutional causes. For while the mean temperature of 1864 was slightly lower than that of last year, part of 1867 undoubtedly exceeded in severity the winter of 1864, and very much that of the winters 1865 and 1866.

The number of deaths from convulsions, 610, being largely attributable, in our experience, to deficient attention to the feeding and other sanitary requirements of infants, demands attention.

Another matter requiring careful consideration at the hands of the authorities and the profession, is the reappearance in Dublin of some cases of cerebro-spinal arachnitis and purpuric fever; we trust, however, that diligence in seeking out and removing those causes, which operate prejudicially upon the public health, will be shown by the authorities, and we feel convinced that great good will attend such measures in these last named disorders, as well as in so many others.

In conclusion, we would observe, that Dublin offers many facilities for the improvement of its sanitary condition, which, notwithstanding those remediable matters, to some of which we have adverted above, has not, on the whole, been unsatisfactory during the year just closed. Our reasons for this deduction are, however, not such as should induce us to take much credit to ourselves, but rather such as should rouse us to more activity in promoting the sanitary, and, therefore, the social and moral well-being of our fellow-citizens. For, notwithstanding the heavy death-rate arising from preventible zymotic diseases, and those other diseases also dependant upon deficient sanitary care, Dublin presents altogether, thanks to its favourable climate and healthful position, as we have said above, a not unsatisfactory general result.

[1] Since the above was printed, the Sanitary Committee of the Corporation have directed inspection of the premises alluded to, which will we trust be followed by prompt measures.

Notes on Current Topics.

The Public Health.

IN the third week of the year the annual rate of mortality in the large towns was 28 per 1000 persons living. It was 27 per 1000 in London, 28 in Edinburgh, and 31 in Dublin; 27 in Bristol, 24 in Birmingham, 36 in Liverpool, 32 in Manchester, 30 in Salford, 26 in Sheffield, 25 in Bradford, 24 in Leeds, 27 in Hull, 28 in Newcastle-upon-Tyne, and 32 in Glasgow. We are glad to find that the

mortality of London continues below the average—the number of deaths registered being 1596, which is 149 less than the estimated number for that week, which, if corrected for increase of population, should be 1745. We select, according to our custom, a few of the more important items from the official returns :—

"Three hundred and seventeen deaths were caused by zymotic diseases, the corrected average number being 355. Thirty-three deaths occurred from small-pox, 37 from measles, 36 from scarlatina, 9 from diphtheria, 73 from whooping-cough, 50 from typhus, and 14 from diarrhœa. One death from small-pox occurred in the West, 14 fatal cases were registered in the North (where the Small-pox Hospital is situated), 8 in the Central, 4 in the East, and 6 in the South districts. Measles was less fatal in the East districts. Ten deaths from scarlatina were recorded in the West, 13 in the North, 2 in the Central, 4 in the East, and 7 in the South districts. Ten deaths from whooping-cough were registered in the West, 15 in the North, 8 in the Central, 14 in the East, and 26 in the South districts. Three fatal cases of fever were recorded in the West, 12 in the North (where the London Fever Hospital is situated), 8 in the Central, 12 in the East, and 15 in the South districts. Phthisis proved fatal to 186 persons, 235 deaths occurred from bronchitis, 92 from pneumonia, and 91 from diseases of the heart.

The East-End of London.

In the midst of the great distress at the East-end of the metropolis—a distress, be it said, greatly alleviated by the noble charity it has called forth, and which seems in danger of abuse—it is satisfactory to learn, upon the evidence of reliable statistics, that the mortality of the district has not increased. We take the following from the Registrar-General's weekly return :—

"In East London, comprising the districts of Shoreditch, Bethnal-green, Whitechapel, St. George-in-the-East, Stepney, Mile-end Old-town, and Poplar, the deaths in the week were 321. This is less by seven than the average deaths of the corresponding weeks of the ten years 1858-67, the average being 328, which if corrected in the usual way for increase of population, becomes 356. The actual deaths were 321. The annual rate of mortality was 27 per 1000 in East London, 27 in West London, 27 in North London, 26 in South London, and 29 in Central London. Allowing for any possible decrease of population in East London, it is evident that the mortality there is not higher than it is in the rest of the metropolis."

A Substitute for Coal.

Some trials have been made at Woolwich Arsenal, by order of the Secretary for War, of bitumen as a substitute for coal in the manufacture of gas. It was found that gas made from bitumen was equal or superior to coal gas in illuminating power, and was more easily extracted. Further experiments showed that bitumen might prove an excellent fuel, its heating power being very great. It is calculated that this substance may be a safe resource as an investment. The War Department, in consequence of these results, has ordered 200 tons for use at the arsenal, and we may, possibly, shortly hear the result of further experimentation. If we do not anticipate that bitumen would compensate for a failure of the coal mines, we may be glad to find it succeed for purposes of this kind. Improvement in the quality of gas is certainly sadly needed.

The Sorrows of Sewage.

There are, at the present time, several towns "under sequestration." They have drained into their rivers, and actions have been brought to restrain them from injuring property, and so forth. What can they do? The streams are polluted, but how can they help that? Irrigation, say some, but the works necessary for that cannot be made in a day. Separate the solids from the liquids, cry others; but the same objection applies, to say nothing of others. Besides, supporting any new scheme to be agreed upon, how can the local authorities know what will be the result. Really for the tax-payers it is a very hard case, however much it may amuse engineers, and it ought to be remembered that it is the engineers who are too often to blame. Have they been urged by a blind enthusiasm, or have they been too anxious to secure work for themselves and the contractors they are in the habit of recommending? Oh! for a minister of health, in the person of some Doctor, who has devoted a life to the study of sanitary matters.

Vital Statistics of Rome.

The Chancelier Générale of Rome has commenced the issue of some vital statistics of the city. It appears that in a population, 215,573, there were in the first eleven days of the year, 214 births and 304 deaths. We would urge on the Marchese de Cinque that he might contribute much to the welfare of the city by extending the important information thus collected. A reliable set of meteorological data would be esteemed throughout Europe, and statistics of the causes of death would call forth the thanks of sanitarians, in all countries, and perhaps, lead to reforms, where they are so urgently needed.

The Hospitals of Vienna.

On the 11th December, 1867, the number of patients in the Hospitals of Vienna was as follows :—

There were in the General Hospital, 1812 patients (1022 male, 790 female); in the Wiedner Hospital, 600 (325 male, 275 female); in the Rudolphstiftung, 742 (443 male, 299 female); in the hospital of the Brethren of Charity, 194; in the Hospital of Ste. Anne for Children, 89, 7 being cases of small-pox, 3 of scarlet fever, 2 of morbilli, 1 of typhus. There were, therefore, 3437 patients accommodated in 5 hospitals, the number of inhabitants of Vienna is a little over half a million.

Mrs. Faraday.

A powerful appeal has been made to the Government to continue the pension of the late Professor Faraday to his widow. Faraday, in spite of the numerous discoveries which might have enriched him, had he been a seeker after wealth, died poor. That fact ought to be sufficient to secure the favour of those who regulate these matters. The simple-minded philosopher has passed away, leaving us the heritage of his noble example. Shall not the nation whose virtues he practised and whose vices he avoided, take charge of the lady who cheered him in his pilgrimage, and who remains to test the value set upon his worth and his services?

Clinical Communions.

We learn from an advertisement that this name has been adopted by one of the largest makers of church and academic robes; for a bag, they have introduced, "containing all the requisites for the administration of the Holy Communion to the sick, to take the place of the inappropriate and toy-like pocket services at present in use." Perhaps it is the habitual use of the word clinical in other senses; but we confess the advertisement looks odd to medical men unskilled in church æsthetics.

St. Andrews Medical Graduates' Association.

THE next General Session of the Association will be held in London on the 8th of April. The chief subject for discussion will be, "What should be the legal definition of Insanity?" At first it was thought that one general session yearly would serve all purposes of the Association, but, on mature consideration, and no doubt encouraged to a great extent by the success already attained, the Council has determined on holding another assembly in spring. We cordially wish them as brilliant a session as the last, and that by that time they may have secured their franchise. The subject chosen for discussion is a large and important one. There are many St. Andrews men who possess a high reputation for their acquaintance with it, and we trust they will come forward and take part in the discussion.

Condy's Fluid.

THE French Minister of Agriculture, Commerce, and Public Works, has, on the recommendation of the Consulting Committee of Public Hygiene, after due inquiry and examination, authorised the sale in France of Condy's Fluid, for the purification of decayed meat and tainted water, in addition to the usual purposes of disinfection.

Coming so soon after the inquest on a woman said to have died from eating poisoned goose (reported in our last week's number), at which it was stated that three cases had occurred wherein vomiting and purging had been caused by eating tainted salmon, this decision is of considerable interest. The subject is sufficiently important to make it very desirable that full details of those cases should be published in order that their bearing on the question of the value of Condy's Fluid, as a means of restoring soundness to tainted provisions, may appear. We should be very glad to place sufficient space at the disposal of Professor Rodgers for this purpose—the more as we have heard from other sources that proper treatment by Condy's Fluid is most effectual as a preservative against the dangers of tainted meat.

WE are sorry to see that the medical interest is likely to be divided in the election of a Coroner for West Middlesex. Mr. Brown, as we anticipated, will retire, but Drs. Hardwicke and Diplock both seem determined to go to the poll. We should be very glad indeed to learn that an arrangement had been made likely to lead to a triumph of the principle that only a medical man ought to hold this office.

DR. LANKESTER is indignant with the Government for not producing prisoners before the Coroner's jury on their way to or from the Police Court. Many will at once conclude that an attempt is being made to diminish the influence of the Coroner's Court. We do not, however, fear this; but imagine that it is entirely a matter of public convenience, and one within the competence of the Home Secretary to dispose of.

A CORRESPONDENT of the *United Service Gazette* calls attention to the distinctions in respect of honours between the French and English services:—An Imperial decree in the *Moniteur* makes seven promotions to the rank of officer in the Legion of Honour, and 34 nominations to the dignity of Knight in the same Order, for acts of devotedness in Algeria during the last epidemic of cholera. The military medal is conferred on 43 soldiers; while to civilians have been awarded 32 gold, 25 silver, and 12 bronze medals for similar services. How gratifying to the recipients! how different to the flimsy acknowledgments made by our own Government to those of their medical officers who have done the State some service unflinchingly! For example, see the following, received by a relative of mine from a P. M. O., India:—

"SIR,—Having on a recent occasion brought to the notice of the Director-General the able way in which you performed your duties during the recent outbreak of cholera, I have the pleasure to forward the answer to the same at his request."

The answer:—

"I have the honour to request you will convey to —— the expression of the Director-General's qualification at receiving such a favourable report of his conduct; and to add the pleasure it has afforded Sir James Gibson to direct that the same may be noted in the record of his services."

A cross or medal, if it were but the size and cost of a farthing, would, I believe, have been far more acceptable and gratifying.

Society Proceedings.

SURGICAL SOCIETY OF IRELAND.

Dr. ADAMS, President of the College, in the Chair.

(Continued from page 81.)

ON reviewing the symptoms and pathological appearances of this case, the following observations suggested themselves to me as worthy of consideration:—

1. The apparent good health of the patient up to the very night on which the disease set in, and the suddenness of the attack. In this respect, however, the case formed no exception to the general rule.

2. The early accession of a state resembling coma, which, however, was not true coma; the pupils were not dilated, and the patient was somewhat conscious. This also was observed in other cases.

3. The ascending and descending character of the respiration, accompanied by a somewhat similar condition of the pulse; this combined peculiarity being most distinctly marked on the first day, and gradually decreasing till the evening of the third, when it was not perceptible. This kind of respiration does not appear to have been observed in other cases.

4. The symptoms of arachnitis so little commensurate with the amount of cerebro-spinal lesion.

5. The little disturbance manifested in the circulatory system except at the very first; and its almost normal condition on the evening of the second day, when, I have noted that, "the pulse was down to 90, and was full, strong, and almost deserving the description of being regular."

6. The absence of many symptoms indicating the typhus condition; the pulse not rising above 112, except at intervals on the first day; the temperature (which I regret was not taken earlier) not rising beyond 101°·4 between the evening of the second day, and the morning of the fourth or last; the absence of typhus prostration, of floccitatio and subsultus tendinum, of the tremulous tongue, and of deficiency or feebleness of the first sound of the heart, although there seems to have been sufficient time for these symptoms to have been developed when one considers the rapid course of the disease.

7. The patient's apparently favourable condition on the morning of the fourth day, and yet his rapid sinking, and death, without any known adjunct cause, on the evening of the same day.

8. The fact, that this case is an example of those in which the dark spots are combined with signs of inflammation of the cerebro-spinal membranes.

This last observation leads to a consideration of the nature of the epidemic, of which this case was an example. Was the case one of purpura maligna, or of cerebro-spinal arachnitis, or a combination of both, or are we to consider these two terms synonymous? The question of the identity of, or necessary connection between, cerebro-spinal arachnitis and that epidemic

disease characterised by dark purplish spots, has already been much debated.

When one frequently sees cases of extensive purpuric extravasations, combined with signs and symptoms of inflammation of the membranes of the brain and spinal cord, it is at first a very natural conclusion to arrive at that these two conditions are necessarily connected as parts of the same disease. But such a conclusion may or may not be correct. I should be slow to accept it till we had further proof of its truth. If it were true, we should expect that in every case which has lasted sufficiently long, there would be some appearances, however slight, of inflammation; but there are many cases on record in which there was not the least appearance of such a condition. I myself published such a case in THE MEDICAL PRESS AND CIRCULAR last April.

In that case there was not the least trace of inflammation in any of its stages, and in this statement I will be supported by my colleagues who assisted me to make the examination of the body. There was some congestion of the larger veins of the cranial and spinal membranes, but there was a total absence of capillary congestion. Moreover, all the organs of the body which I examined were congested, and why might not the condition of the cerebro-spinal membranes in that particular case have merely shown that they formed no exception to the state of the other organs? I do not say that I believe this to be the case, but proof to the contrary is wanting.

It seems to me—

1. That the disease is primarily and essentially a specific blood-poisoning.

2. That, as certain other blood poisons have a special tendency to induce inflammation of certain parts of the body, so the poison of the disease in question has a peculiar tendency to induce inflammation of the cerebro-spinal membranes.

3. That the disease may run its course without any such complication.

CEREBRO-SPINAL BLOOD-POISONING.

Dr. HEWITT then read the following paper:—

I wish to draw the Society's attention to the following case of cerebro-spinal blood-poisoning, as affording an instance of the absence of any inflammatory product, in a case which presented marked symptoms of the so-called cerebro-spinal arachnitis. I made the post-mortem at the request of my esteemed colleague, Mr. Croly, and to him I am indebted for the notes of the case during life, as recorded by Mr. Brown, the Purser student.

On the morning of the 12th November, 1867, a boy named Terence Byrne, was brought to the Dispensary of the City of Dublin Hospital, where he was presented for treatment to Mr. Croly. Even at that time there were evidences of the serious nature of the case, in a peculiar stiffness of the muscles of the neck, and a slight retraction of the head, and Mr. Croly pointed out the case to the class, as being most likely to prove one of malignant purpura. Notwithstanding the warning given to the parents, as to the dangerous nature of the case, they made light of it, and took the boy home, where he hourly grew worse, and at two o'clock in the morning of the 13th November, he was admitted into the hospital, when his state was as follows:—

His head was forcibly retracted, and the muscles of the neck were rigid; his eyes had a wild staring appearance; the pupils were widely dilated, and almost insensible to light. There were a few dark plum-coloured spots, of very irregular shape, scattered over the left hip and under the right axilla. These did not disappear on pressure. The pulse was very fast, and so irregular that it could not be counted. When spoken to, he seemed perfectly unconscious. He screamed continually, and from the motion of his hand to his head, the distress appeared to be localized there. He could not be kept quiet, even for a moment, but was incessantly tossing his arms and legs to and fro, and turning from side to side in the bed. Three grains of calomel were placed far back on the dorsum of his tongue; and it was attempted to administer small quantities of wine, but it was found impossible from the violent restlessness of the patient, to get him to swallow. Enemata of small bulk, consisting of strong beef-tea and wine, were administered. Some of his hair was removed, and a cold lotion was applied to his head. Dr. Chapman's ice-bag was next tried. Applied along the cervical and upper dorsal spines, it, for some short time, seemed to afford relief, but he soon became worse, and after a short period of convulsive jactitation, he became comatose, and in half an hour died without a struggle.

Autopsy seven hours after death.—Rigor mortis was fully established. The fingers were clenched, and were of a diffuse plum-colour, which on pressure disappeared and returned slowly on removing the pressure. The same discolouration extended over the posterior and external aspect of both arms, and, in a less degree, was visible on the legs, thighs and loins. The spots observed before death are still evident, though less distinct; they do not disappear on pressure.

The cerebral sinuses were engorged with very dark blood, which was very faintly coagulable.

The veins of the dura mater were also greatly congested, and those on the brain, especially at the posterior and inferior portions of the cerebellum, were loaded with blood. There was no opacity or thickening of the arachnoid in any part, nor was there a trace of any exudation into the sub-arachnoid space.

The substance of the brain was of normal consistence, and was not much congested. The lateral ventricles contained, each, about half a drachm, or more, of a turbid, slightly bloody serum. The corpora striata, and optic thalami were healthy.

When the vertebral veins were cut across, in taking out the brain, a large quantity of fluid blood oozed from them, and after a few minutes, a great many bubbles of gas, which made the blood assume a frothy appearance, this was more evident at the right side.

The cervical portion of the spinal cord alone could be examined, as the relatives were most anxious that as little as possible should be done, but not a trace of any exudation was visible; the arachnoid membrane was perfectly transparent, but there was considerable congestion of the vessels of the pia-mater.

In the commencement of this paper, I have advisedly called the disease cerebro-spinal blood-poisoning, to avoid adopting a name which, I conceive, conveys a wrong notion as to the pathology of the disease; namely, that it is a cerebro-spinal arachnitis.

Now, not only is this not so, for several of the published cases indicate an entire absence of any symptom which would indicate such inflammation during life, and merely some congestion in the nervous centres, after death, (and these very often are the worst and most rapidly fatal cases), but I conceive that a careful review of all the cases will convince any thoughtful mind, that what we have to deal with is not so much an acute inflammation of the brain and spinal cord, as a malignant blood-poisoning, which, very frequently, I grant, but not invariably, produces a secondary effect on the small vessels of the cerebral and spinal pia mater; giving rise to congestion, and finally to exudation, in those cases that live sufficiently long to allow of its taking place. And, indeed, in those cases in which I have seen an exudation, it has been either purulent, or, at most, an extremely cacoplastic form of lymph, such as you may see in the pleura or pericardium, in cases of blood-poisoning, and not that organizable product, which is wont to be the result of idiopathic acute inflammation. Once more, it has been very generally observed, that measles, typhus fever, scarlatina and other diseases, have, of late, exhibited a tendency to be complicated with a cutaneous eruption, very similar to that of the cerebro-spinal disease, and have even, in many instances, proceeded rapidly to a fatal termination, and even, in not a few instances, shown signs of pain in the head and neck, muscular rigidity, &c., which denote a departure from their normal course.

Now these very diseases have long been recognized as blood diseases, and a due allowance is made for differences in their phenomena produced by difference in the individual affected, or the epidemic. But while we thus have allowed for the alteration which may be produced by the individual, have we sufficiently taken into account the changes that may occur in the blood-poison. Are the poisons of these diseases subject to no change? I think that when we consider how mutable all organic compounds are, and how easily they are broken up into others, we must allow that it is at least very possible that they may undergo such alteration as may render them capable of producing effects that they would not otherwise do.

I would thus explain the abnormal and virulent type that some blood diseases have assumed during the last two years, and I see nothing more likely to account for this apparently new disease, than that some blood-poison, be it that of cholera, typhus, or measles, should undergo some decomposition which would render it capable of altering the blood in so profound a manner as to render it unfit for the healthy nutrition of the nervous system. And here I may draw attention to a circumstance in this case which may serve to indicate the alteration in the blood, namely—the presence of gas in the veins. It was

observed only in the vertebral veins in this case, but in another case in which I made an autopsy with my colleague, Dr. John Hawtrey Benson, we observed bubbles of gas in some of the cerebral veins, and in the internal mammary vein.

It has been objected to the view given above, that many of the cases exhibit, from the first, most marked symptoms of so-called cerebro-spinal arachnitis, and that it was not till late that the cutaneous affection has appeared, if, indeed, it has appeared at all. To this I answer, that in some cases which have exhibited the above-mentioned symptoms in a marked manner, and have proved rapidly fatal, there has been observed rather congestion or purulent exudation, than incipient inflammation or organizable lymph.

Again, those who favour the theory of inflammation have never offered a very rational explanation of the cause of the eruption. Some have thrown out the idea that it is produced by the effect of the inflamed spinal system on the sympathetic, which governs the capillary circulation. But why, I demand, is it reserved for this late period to discover, when spinal or cerebral meningitis never produced such an eruption before?

Of the two hypotheses, I think the one that best explains all the phenomena of the disease is that which regards it as due to a poisoning of the blood; at least, so far as our knowledge of the disease at present extends. It behoves us, however, to lose no opportunity of studying this disease, and while I have put forward these ideas as to the nature of this affection, I do so in no dogmatic spirit, but as conveying my own impressions as to the bearing of the facts at present within our reach.

With regard to treatment, if it be true that the disease is due to a deterioration of the blood, which may produce a local exudation of a purulent or cacoplastic nature, it will be evident that there is little use in drenching your patient with mercury, or in any form of active depletion. Much more good may be done by iodide of potassium, or bromide of potassium, combined with small quantities of belladonna and opium, the former to counteract the injurious effect of the latter while aiding its action, by stimulants and nourishing diet, and I must confess that I think there are many cases where the spinal ice-bag will check one of the tendencies to death, while it affords time for nature to exert his sway, and gain the upper hand. I do not expect from this, or any other remedy, more than occasional success, but I am firmly persuaded that it, at least, deserves a trial at our hands, and I have, in one or two cases, witnessed the power of this remedial agent, for which we are indebted to Dr. Chapman's unwearied zeal and energy.

Mr. JOHN MORGAN asked how long Dr. Hewitt kept up the application of the ice-bag? He had lately had a case of this kind, and treated it with the ice-bag with the happiest results. The case was similar to that detailed by Dr. Hewitt—the child was about the same age, had dilated pupils and all the other symptoms. He applied the ice-bag very early, within a few hours after the patient was admitted to hospital. The pupils were dilated as widely as possible, but the very instant the ice-bag was applied, they contracted, just as rapidly as a ray of light would make the pupil contract. There was a remarkable appearance on the skin. The boy had about five spots of purpura on his thigh, about the size of the head of a large pin, and a blush over the entire surface of the body. The very moment the ice-bag was applied the blush disappeared. As soon as the ice melted, the blush began to return, at least during the first twelve or eighteen hours; and as soon as he put on a fresh ice-bag it disappeared. In this case the ice-bag was kept constantly applied for three days, until the patient was out of danger, and the higher the ice was placed over the spine the greater was the effect produced.

Dr. HENRY KENNEDY said, as far as his present knowledge went, he sided with the authors of the two cases brought forward that evening. The epidemic described by Dr. Darby and the late Dr. Mayne, was one of great fatality, often running its course in two or three days, and presenting the most intense form of cerebro-spinal inflammation; and yet it was certain that no purple spots existed in those cases. Dr. Kennedy proceeded to say that three years since, cases of well marked cerebro-spinal arachnitis began to be admitted into the wards of the Cork-street Hospital, and have continued to be admitted occasionally ever since. The great majority of these cases had no spots whatever, and what was specially worthy of notice, were very generally amenable to treatment. On the contrary, the few cases he had seen, where the disease with the purple spots existed, were nearly all fatal. It was a fact, too, that cases of the disease with the spots had been met, and yet no arachnitis was found after death. One such case had been given that evening. And this reminded him that in any of the acute fevers, such as scarlatina or typhus, where the disease ran its course with great rapidity, all that was found after death was violent congestions, attended with more or less serious effusions, very similar indeed to the new disease. The evidences of inflammation, which he allowed had been very frequently present, he considered as being superadded phenomena. As to the treatment he believed it might be more antiphlogistic than was commonly thought advisable. He had used leeches with mercury, and at the same time gave wine, and had no reason to be dissatisfied with that method of treatment. Some of the cases attended with spots recovered by these means from the comatose or acute stage, but died after some weeks from hydrocephalus.

Dr. CROLY said he had seen the first case of this disease which occurred in Dublin, the case being that of a pupil of his own, living in his (Dr. Croly's) house. The young man was in rude health up to Sunday, the 18th March, the year before last. He complained of rigors and general febrile disturbance, and on Sunday night, without the slightest symptoms of cerebro-spinal arachnitis having manifested themselves, the purple spots made their appearance. On noticing an injected condition of the conjunctiva, and a general look as if infected by the poison of typhus, he examined him for spots, and found a number of spots of a magenta colour on the arm. They increased to a large size, and he sought the aid of Dr. Benson. Dr. Benson did not exactly know what to term the disease. He supposed it might be some violent form of purpura. The symptoms continuing, Dr. Stokes saw the case in the morning with Dr. Benson, when he said that he thought he had known every Irish disease, but he had that day learned a new one. This patient died within twenty-four hours without one symptom of spinal arachnitis. He (Dr. Croly) had no doubt that he died of blood-poisoning. The moment he saw him ill he put warm applications to his feet, gave him brandy, applied mustard to the extremities, and injected brandy and quinine into the rectum. The excessive vomiting prevented any mercury being given by the mouth, and unless it were rapidly rubbed in through the skin, it could not have been administered. He was unfortunate enough to see six cases of this disease, which he described in the College of Physicians, and in all the six cases death was very rapid, and there were very few symptoms of cerebro-spinal arachnitis. He was decidedly of opinion that purpuric fever and cerebro-spinal arachnitis were distinct diseases; and that if the latter made its appearance in those cases where the purple spots existed, it was only a complication.

Dr. MAPOTHER said the epidemic first appeared in the barracks of Versailles, and in other French towns, in the year 1836, and it then presented no purpuric spots. In 1865 it appeared in West Prussia, and Dr. Saunderson had recorded several cases of that epidemic, and there were but few of them with purpuric spots. The same was to be said of the American outbreaks of the disease. As to the question of the identity of the cerebro-spinal and purpuric forms, Mr. Rainey had stated his opinion that in no places did the sympathetic filaments abound more than in the arachnoid membrane. Inflammation of that structure, therefore, might readily influence the vasa motor function of the sympathetic system, and lead to effusion of blood. In the discussion which took place at the Epidemiological Society, Dr. E. Crisp stated the very remarkable fact that pigs can be given this disease by being fed on any of the flesh of animals that had died of splenic apoplexy or braxy, and it had been proved by Du Vaine that braxy was due to the entrance of bacteria into the blood from the air of the field in which the animals fed. He (Dr. Mapother) had obtained in Paris a beautiful specimen of bacteria in the blood of an ox which had died of splenic apoplexy. Dr. Crisp's assertion it would be well to verify or refute.

Dr. JACOB, referring to the interesting pathological specimen which Dr. Croly had shown, said he had occasion lately to extract an ossific cataract from a man. This form of disease occurs principally when the lens is dislocated into the anterior chamber, and remains there. On diagnosing the case he did not know there was lenticular calcification, and only perceived it on passing in the knife. The lens was analyzed by his friend, Dr. Mapother, who found it principally composed of calcareous matter with some phosphates. It was not associated with a gouty diathesis as would have been naturally expected, and it was a change that seemed to be dependant on the removal of the natural vascular supply from the lens.

Dr. MAPOTHER said he found that the cataract alluded to by Dr. Jacob, disappeared in effervescence on the application of

acetic acid. This case seemed to show, that a body like the lens when removed into the anterior chamber, and deprived of any vascular supply, could nevertheless undergo an ossific change. Those parts which were least vascular, were the most likely to be thus affected, and these were not blood changes but chemical alterations in the tissue. Every one of the tisseus contain a considerable quantity of lime salts, and by the removal of the other constituents of the lens, these salts form, as it were, a lenticular skeleton. Dr. Croly's case was interesting as showing ossification in the vitreous humour.

Dr. HEWITT asked if Dr. Jacob's specimen was hollow?

Dr. JACOB said, it was not perfectly hollow; there was a plate of apparent bone, but some of the lens matter was there also.

Dr. STAPLETON asked Dr. Mapother whether he meant ossification or calcification?

Dr. MAPOTHER replied that he meant calcification.

The meeting then adjourned.

Address.

LESIONS OF CUTANEOUS SENSIBILITY IN DISEASE.

THE INAUGURAL ADDRESS DELIVERED IN THE DINING HALL OF TRINITY COLLEGE.

JANUARY 21, 1868.

By E. W. COLLINS, B.A. Med. Sch.

AUDITOR OF THE DUBLIN UNIVERSITY MEDICO-CHIRURGICAL SOCIETY.

MR. PRESIDENT AND GENTLEMEN—Our age is one of progress. Few are the minds its influence has not reached, cold is the breast its spirit has not animated. "The reason of man," said the eloquent Graves,[1] "is now more fully employed than at any former period. Her empire extending from the old to the new world, from Europe to our antipodes, has encircled the earth: the sun never sets upon her dominions—individuals must rest, but the collective intelligence of the species never sleeps: at the moment one nation, wearied by the toils of day, welcomes the shades of night, and lies down to seek repose, another arises to hail the light of morning, and refreshed, speeds the noble work of science." Yet, in the midst of a progress so universal, and in none more remarkably exemplified than in our own profession, there are to be found those who would have us believe that the healing art is lagging behind. How false such an opinion, so frequently refuted, is, it is not my purpose here to inquire. Enough be it for us that in thus meeting together we witness against it: for, we hail with joy the formation of that society whose birth we have assembled to celebrate. The offspring of progress, we bid it welcome in this hall which has been the cradle of so many of its kindred. For, as a germ long bedded in a barren soil, at length under the influence of milder suns and vernal showers, unfolds its tender bud, even so the germ of our society, long latent, has unfolded itself under the warm influence of the late progress of our school—a progress in which we recognize, as it is no less our duty than it is our pleasure to bear witness, the untiring energy and the self-sacrificing devotion of one who so ably fills the position of University Anatomist. To this great cause we would fain ascribe the yearnings which prompted to the formation of this society; and hence, undoubtedly, it was that within the past few months this project came to be seriously entertained. Its promotion was entrusted to a Provisional Committee of students in medicine: their fellow-students were invited to co-operate with them: and the objects contemplated in the formation of the society were submitted to the Board of the University. Shall I say that those objects met with its approval? They met rather with its hearty support. Nor can I select a more fitting opportunity than this for returning the thanks of the society to the Provost and Board of Trinity College for the liberal and kindly feelings they have manifested towards it at its birth. That such friendly sympathies may be long continued towards it, and that it may not be unworthy of them, shall be, we fondly trust, its earnest endeavour. The society, established under these auspices, next proceeded to the election of its officers, and determined on holding its Inaugural Meeting early in the succeeding year. How far its efforts in this respect has succeeded your presence to-night is a proof. Its pleasures alone are alloyed by the absence from our midst of one who, with an eloquence peculiarly his own, has so long wielded the sceptre of surgery in this school. Our earnest desire is that ere long he may be granted to reappear among us, with renewed health and renewed vigour, to resume that sceptre which he wielded so well; and, our prayer for him is, as for Augustus was that of the Roman bard of old

Serus in cœlum redeas, diuque
Lætus intersis populo Quirino,
Neve te nostris vitiis iniquum
Ocior aura
Tollat—1

Among the objects which our society has for its aim is the reading of essays to be followed by debates, on subjects connected with medicine and surgery and the allied collateral sciences. But I should be sorry to think that these, though our chief, should be our only objects in thus meeting together. What a wholesome stimulus shall we not each experience in our pursuit of knowledge? How much closer shall not our connection be one with the other? What friendships may I not say it will foster, what differences remove? And, drawn thus closely together during the short, aye too short, period of our student life, it may not be too much to hope that the same friendships, the same kindly feelings, the same desire for mutual improvement and encouragement, thus engendered, and withal the same freedom of thought, will animate us when no longer students within these walls. Nor can we overlook the great advantage to ourselves of such a society in enabling us, while students, when much is not demanded of us, to bring together our scattered ideas and communicate them; to improve and harmonize our modes of thought and of expression; to cultivate conciseness of language, so as, while avoiding all that is superfluous, to leave unsaid nothing of importance; to correct all errors of style and inelegancies of delivery. The necessity indeed of such a society must be evident to all, not alone those belonging to, but those outside the rank of students. We propose no imaginary benefit. Similar societies exist in connection with the Colleges of Physicians and of Surgeons and other medical schools, which each and all have shed a lustre on those bodies. This school, united as it is by so many ties with our University, especially demands it. Among the many advantages which it possesses let us not allow this to be one of the least. We believe that such a society was wanting, nay more, that it will succeed. Yet, if we desire its success, there are certain principles that should guide us in pursuing our inquiries and in examining our conclusions. Such advice it would be as unbecoming as distasteful in me, one of your number, to offer to you, crude and undigested as it necessarily should be. I shall lay before you rather the experience of one whose high culture and reputation alike demand for him your respect.

"If," says Abercrombie,[2] "we would contribute something towards diminishing the uncertainty of medical researches and introducing a greater degree of precision into medical reasonings, there are certain rules which we ought to keep steadily in view in conducting our own inquiries and in examining the investigations of others.

"First, we should endeavour to have all our terms fully and distinctly defined. Secondly, in making a statement of facts, or in examining a statement of another, we should be satisfied that the facts are authentic; that they are fully and fairly stated, and that no important facts are left out of view, disguised, or modified. It is also necessary that no facts not really connected with the subject be taken into the statement. Thirdly,"—and on this he lays great stress—"when we find two events placed in a state of contiguity to each other, we should use the utmost caution in considering them connected in the manner of cause and effect. Fourthly, in deducing general conclusions or general doctrines, we must beware on the one hand of assuming imaginary principles which cannot be proved really to exist, and on the other of deducing principles or doctrines from a limited number of facts. Finally, in examining a statement made by a writer there is cause for exercising similar caution." The rules thus shortly proposed he submits with diffidence as those which should guide us in our inquiries. Without constant attention to them numerous facts may pass before us from which we may derive no knowledge; and many ingenious and plausible doctrines may be presented which tend only to lead us into error. "In the same manner," he continues, "the benefit which a physician derives from his own opportunities of

1 Clin. Lects. on Practice of Medicine.

1 Horace, Carm. I. 2, 45.

2 Treatise on the Intellectual Powers.

observation is not in proportion to the period of time over which it has extended, or the number of facts which have passed under his view, it must depend on the attention with which he has observed these facts and traced their relations to each other, and the caution with which he has ventured on assuming the relation of cause and effect, or has advanced to general principles. It must depend further on the jealousy and suspicion with which he has received even his own conclusions, and the care with which he has corrected them from time to time by further observations. The farther a physician advances in the course of rigid inquiry, he becomes more sensible of the difficulties with which his science is encumbered, more suspicious of all general conclusions, and more anxious to bring them to the test of minute and extensive observation; in particular he learns to exercise more and more caution in considering any one event in medicine as the cause of another. In real acquisition consequently his progress is slow: for much of this improvement consists in detecting the fallacy of systems which he once considered as established, and the instability of principles in which he once confided as infallible. But these discoveries prepare the way for actual progress, and the conclusions at which he does arrive then fall upon his mind with all the authority of truth."

Not long since it was my privilege to listen to an address delivered by the talented Auditor of the Junior Philosophical Society[1] on the subject of Æsthetic Culture—an address remarkable for the richness of its language, for the elegance of its style, still more, for the ideas which it embodied. A thought, thus suggested, arose that for us this subject is capable of a still wider acceptation, and that on this occasion some notices of cutaneous sensibility, in connection with its exaltation and diminution in disease, may not be devoid of practical interest. Yet no one can feel more sensibly than I do how unworthy I am to address such an audience on such a theme. I have undertaken the task in no spirit of presumption, and I approach its consideration with no small misgivings.

"We find every organ of sense," wrote the illustrious Bell[2] "with the exception of that of touch, more perfect in brutes than in man. In the eagle, hawk, gazelle, and feline tribe, the perfection of the eye is admirable: in the dog, wolf, hyena, and birds of prey, the sense of smell is inconceivably acute: and, if we hesitate to assign a more exquisite sense of taste to the inferior animals, we cannot doubt their superiority in that of hearing. But in the sense of touch *man* claims the superiority."

Our notions of sensibility are formed from that of the skin; and, so familiar are we with the painful effects of injuries upon the surface, that all are prone to imagine that the deeper the injury the more dreadful the pain. Yet such is not the fact. The sensibility to pain varies with the function of the part. To such irritants as would give the skin pain the internal parts are wholly insensible. Their peculiar sensibility is dependent on the functions they perform. I can illustrate this no better than by referring to the insensibility to touch of the great centre of organic life.

It is on record that a noble youth of the family of Montgomery, from a fall and consequent abscess upon the side of his chest, had the interior marvellously exposed. Harvey thus relates an interview that he had with him at the request of Charles I. "When I had paid my respects to this young nobleman, and conveyed to him the king's request, he made no concealment, but exposed the left side of his breast, when I saw a cavity into which I could introduce my fingers and thumb. Astonished with the novelty again and again I explored the wound, and, first marvelling at the extraordinary nature of the case, I set about the examination of the heart. Taking it in one hand, and placing the finger of the other on the pulse at the wrist, I satisfied myself that it was indeed the heart which I grasped. I then brought him to the king that he might behold and touch so extraordinary a thing, and that he might perceive, as I did, that, unless when we touched the skin, or when he saw our fingers in the cavity, this young nobleman knew not that we touched the heart."

And yet, the heart insensible to touch, is alive to every variation of the circulation, to every alteration of posture or of exertion, and is in sympathy of the strictest kind with the constitutional powers.

Again, sensibility to the varieties of temperature is a different endowment to that of touch or of pain, and sensibility to the stimulus of tickling is a different endowment from either. All these sensations have their seat in the skin, and are merely varieties of cutaneous sensibility.

There is yet another sensation of a very peculiar character—that which accompanies muscular contraction. For, every muscular contraction seems to cause an excitation of the sensitive nerves in its vicinity, and the degree of excitation being in proportion to the degree of energy of the contraction and to the resistance, we have thus an excellent means of judging of the state of the muscles. But this muscular sense strictly does not come within the limits of my subject. I dismiss it therefore from consideration, merely observing that, even if muscles have peculiar nerve-fibres which go up to the brain along the anterior roots, as J. W. Arnold[1] has tried to show, to give there some special sensations in correspondence with the degree of contraction, it seems nevertheless quite certain that the nerves of the other sensitive impressions, which have been mentioned, do not pass by the anterior roots, and that therefore the theory of Sir Charles Bell as regards these remains entire.

The kinds of sensitive impressions therefore which may come from the various portions of the body, leaving out of consideration the four higher senses, the peculiar sensation given by the genital organs, and the muscular sense, are those of touch, tickling, heat and cold, and pain. The nerve-fibres employed in the transmission of each of these, as the researches of Brown Séquard[2] have shown, are as distinct one from the other as they all are from the nerve-fibres employed in the transmission of the orders of the will to the muscles. For there are many cases on record which prove that the loss of each may exist alone. But, though for a long time several cases of this form of anæsthesia have been known, it is only recently that their relation with diseased states of the spinal cord has attracted notice.

For their transmission through the spinal cord to the brain the gray matter is the principal channel. But the question regarding the elements of the gray matter thus employed has not yet received a positive solution. Yet, it cannot be doubted, from late investigations, that this transmission takes place by both nerve-cells and nerve-fibres united together. Most of the nerve-fibres of the posterior roots of the spinal nerves, after having reached the gray matter, attach themselves to the nerve-cells. These cells communicate with others in such a way that two kinds of transmission are possible, the one across the cord, and another towards or from the brain. But besides these there are in the gray matter several collections of longitudinal nerve-fibres forming minute white columns surrounded by the gray substance. These white columns, first well described by Mr. Lockhart Clarke, and subsequently by Prof. Schrœder Van der Kolk, cannot be considered as the only channels in the gray matter for the transmission of sensation and volition, though it is probable they participate in it. It may be, as has been suggested, that they are employed for a peculiar kind of sensitive impressions, while the other impressions would be transmitted by nerve-cells and their communications. Further, the special portions of the gray matter appropriated to the conductors of each remain still undiscovered: and much of this, most unfortunately, is due to neglect in noticing the various kinds of sensibility in disease.

As symptoms of alterations in the spinal marrow, whether as the result of injury or of disease, lesions of sensibility play no unimportant part. Among these lesions may be enumerated morbid increase and diminution of the various kinds of sensibility; perversions, and errors as to the point of starting, of sensitive impressions; and the referring of sensitive impressions to the periphery.

The referring of impressions made on the sensitive nerve-fibres to their peripheral termination, as a symptom of disease of the spinal cord, is full of interest. It seems that most of these conductors possess normally no excitability at all in any part of their course,[3] save at their termination in the skin, with the exception of those of tickling and of pain. But, however this may be, it is of some importance to know that all of them may acquire in an especial degree, if not exclusively, under the influence of inflammation the power of being excitable and of giving sensitive impressions which are referred to the periphery. This change may take place in any part of their length. Thus a large portion of the skin[4] may be the seat of excruciating pain or of burning sensations; and yet the surface which, to the patient's idea, may be the seat of pain, may be altogether insensible. The general con-

4 Sir Charles Bell. The Nervous System.

clusion arrived at by the eminent American physiologist regarding peripheral sensations in spinal diseases is, that, whatever their kind, they are due to changes in the gray matter, the result of inflammation. He tells us further that they occur rarely, and never exist unless the posterior roots are irritated or the cord itself inflamed.

The gray matter in its normal state is not excitable.[1] For a part may be a conductor of sensitive impressions though not endowed with sensibility. As an example, the cerebral lobes are said to be conductors, but they are said not to be impressionable. So is the gray matter of the cord. When it exists alone, as after a transverse section of the white columns, it transmits to the brain the sensitive impressions made upon the parts behind the section: but when irritated, it does not transmit anything, because it is not itself impressionable. Still, though normally not excitable, it acquires the property of being excitable when inflammation has set in. It is then that the pressure of a fractured or dislocated bone acts upon this matter, causing the feeling of formication and pain of various kinds.

Correspondence.

CANNES AND LLANDUDNO AS WINTER RESORTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having just read your notice of a letter in the *Times* signed James Nicol, M.D., comparing the climate of Cannes, in the South of France, with that of Llandudno, in North Wales, I beg to say I know both places well, and think there must be some mistake in the comparative tables given by Dr. Nicol.

In the month of August, 1866, I was staying on a visit at a friend's house at Penmanmawr, with several ladies and gentlemen from London. One day it was proposed we should make up a party to Llandudno. We were very delighted at the idea, and in half an hour the carriage—an open one—was announced to be ready. The son of our host drove us, and was well acquainted with the place we were going to; but to our utter astonishment, when we were getting into the carriage we found it half-filled with rugs, shawls, and cloaks, and, above all, the foot-warmer. Some laughed, some enquired if we were going to the North Pole; but we were treated as ignorant Londoners, who knew nothing, and were compelled to submit to the treatment prescribed; but much as we scorned all the warm wraps, as soon as we got to Llandudno we were only too glad to avail ourselves of the comforts our kind friends had provided. One of the gentlemen of our party, a medical man, was thankful to have a lady's shawl in addition to his great coat, he felt the cold so much. We stayed but a few hours, being almost perished.

Now, to compare such a place with Cannes as a winter resort I do not understand. I ask Dr. Nicol if oranges ripen in winter in North Wales? I have stayed four winters in Cannes, and have had ripe oranges gathered fresh every day from the trees. And when Dr. Nicol can produce this fruit to perfection at Llandudno, or any other place in England, then will I believe that our climate can be compared to Cannes for its warmth of temperature, and not till then.—I am, &c.

A CONSTANT READER.

COOKERY REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—An article on "Cookery Reform" appeared last week, I believe, in your journal, being afterwards copied by several other papers, and, as there is a slight error in it which, to some degree, might injure my interests, I hope you will do me the favour of inserting the following rectification.

One of the paragraphs of the said article says:—

"The Norwegians have shown us the way to reform in this respect, and it has been introduced to the English public, especially with a view to the economy of fuel in the Abyssinian campaign, by Captain Warren, and under the auspices of the Society of Arts."

This must necessarily lead the reader to believe that Captain Warren's cookery stove, and my patent "Norwegian Self-acting Cooking Apparatus," both exhibited at the sametime at the Society of Arts, are one and the same thing. This is, however, not the case. As far as I know, Captain Warren has not taken the idea for constructing his very ingenious and most useful cooking stove from any Norwegian invention, and I should think that he, not less than myself, would wish to have it clearly understood that these two inventions, are in principle and construction entirely different.

Captain Warren's cooking stove is, if I am not mistaken, constructed on the principle of heating by steam generated in a boiler by means of a furnace attached to it. My apparatus, on the contrary, is provided with no furnace, nor any contrivance for producing steam pressure; it cooks away from the fire altogether, and is based on the principle of retaining the heat obtained by fire apart from it, just in the same way as a refrigerator is intended for keeping the heat *out*. Again, Captain Warren's apparatus is, throughout, made of iron; in mine the only part of metal is the saucepan or cooking vessel; his is, if I understand it rightly, more especially adapted for large establishments; mine is a thing for the million, for rich and poor, for the domestic kitchen as well as for persons away from home; it cooks and keeps the food hot just as well when carried about on a pack-saddle, on a cart, or in a fisherman's boat, as in a coal-pit or under the kitchen table.—I am, sir, very respectfully, your obedient servant,

JOHAN SÖRENSEN.

23rd Jan., 1868.

THE ELECTION OF CORONER FOR WEST MIDDLESEX.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Assuming that not only the medical profession but all right-thinking persons beyond it, are agreed as to the importance of a medical knowledge to the proper fulfilment of the important duties of coroner, I need say no more on that head; but I wish to give one little hint to those who are interesting themselves in the forthcoming election, and, indeed, to the candidates themselves. It is this, that while it is most desirable for a medical man to be elected, it is most unwise for a member of the profession who holds a deputy-coronership to put himself in nomination, as the medical element may not thereby be strengthened; for, although the deputy coroner may succeed to the vacant coronership, the vacancy which he leaves open may be filled by a legal candidate.—I am, sir, yours faithfully,

NON-MEDICUS.

MR. CONDY ON INFECTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I see it announced that the lying-in wards of King's College Hospital, have been closed on account of the enormous mortality occasioned by epidemic puerperal fever, and have observed that this most fatal infectious disease has been also very prevalent in other institutions of the kind.

This state of things is, in my opinion, a serious blot on that branch of sanitary science, which relates to disinfection.

If we bear in mind, that in the spread of puerperal fever, whether from one lying-in woman to another, or from patients affected with other infectious diseases, such as erysipelas to puerperal subjects, there is always a local point of *invasion*, while in the former set of cases, there is also a local point of *evasion* of the poison, it must be obvious that few diseases present more favourable conditions for the arrest of infection. It would therefore seem to me that, if it be really necessary to close lying-in wards on account of the prevalence in them of epidemic puerperal fever, one of two things must be the case, namely—either 1. thorough measures of disinfection have not been employed; or, 2. we are not yet in possession of any real practical disinfectant.

But, my confidence, founded on long experiences, in the efficacy of disinfection when thoroughly enforced, is so great, that I cannot but think that in those hospitals in which great mortality has arisen from puerperal fever, disinfecting measures have not been properly applied.

Feeling satisfied that the power of thorough measures of disinfection to prevent the spread of puerperal fever is capable of being demonstrated in institutions wherein those measures can be faithfully carried out, I hereby declare myself willing to undertake the proof of this statement in any lying-in ward suffering from puerperal infection, provided the temporary sanitary management of such ward be placed under my direction.—I am, Sir, yours obediently,

H. B. CONDY.

Battersea, January 22, 1868.

Gleanings.

RELATION OF HEAT TO MENTAL WORK—Experiments by Dr. J. S. LOMBARD, Assistant Professor of Physics in Harvard University.—The object of the first series of investigations was to study the temperature of the head, while sitting quietly by himself, with no special mental occupation. Under these circumstances, it was found that while the temperature of the head was in some instances quite steady, in others it was very variable, rising and falling, often with great rapidity. The variations were slight, not amounting, as a rule, to more than a hundredth of a degree of Centigrade ; but still they were very marked, if some other portion of the body was taken as a standard of comparison; thus the temperature of the leg or arm varied, if at all, within much narrower limits. What the exact cause of these irregularities was, could not be determined with certainty ; but the conclusion arrived at from a great many observations was, that this variability of temperature was connected with certain conditions of the mind. It was found that, in those cases in which the temperature was steady, the mind was, as a rule, in a more or less torpid state, such as persons are apt to fall into after a hearty meal ; while in the cases in which variability of temperature existed, the mental condition was one of much greater activity. The effect of a transition from the former to the latter condition was frequently shown, under the following circumstances :—It often happened, when the mind was in the state of inactivity mentioned, that one or more persons would enter the room in which the observer was seated, and a short conversation ensue. The subjects of conversation were of no particular interest, and required no reflection ; but nevertheless, in a few moments the temperature, which had previously been steady, would begin to vary, rising and falling, but with a general upward tendency. This change was not due to the muscular exertion of talking, for it manifested itself when the observer took no part in the conversation ; merely listening to the words of others, and saying nothing himself. Nor was it owing to any effect produced upon the circulation by modification of the action of the heart, for in this case other portions of the body would have been influenced likewise, whereas it was found that the head alone was affected, other parts situated full as favourably, if not more so, for feeling any such influence, exhibiting little or no change of temperature. Whatever the cause was, it certainly appeared to have its seat in the head.[1] Pursuing these experiments farther, it was found that *anything that aroused the attention* was capable of causing a greater or less rise of temperature on the part of the head, over and above that of the rest of the body. Various sights and sounds had this effect ; and, indeed, it could be produced in a great variety of ways. In the next place, the effect of the exercise of the higher reasoning powers was investigated. The results of these experiments were as follows :—*First.* Mental action of this sort caused a rise of temperature on the part of the head, which varied very much in different cases ; the highest rise noticed did not exceed the twentieth of a degree.[2] *Second.* The temperature of the extremities fell, sometimes only slightly, but at other times very decidedly—a half or a quarter of a degree of Centigrade, for example. This fall was doubtless owing, in part, to the absence of muscular exertion consequent upon sitting still ; but not entirely so, for mere immobility, without mental exertion, did not produce an equally great effect. A large number of observations were also made upon the effect of the reading of different literary productions. Provided the work did not particularly excite the interest or arouse the emotions of the reader, either no effect at all was produced, or else the temperature was slightly depressed. But with productions of an opposite description a very different result was obtained. In these cases the temperature was very speedily and visibly elevated. The most striking effects of all were produced by the reading aloud, or the recitation of poetry. The rise of temperature in this case was not due in any appreciable degree to the muscular exertion involved, for mere mechanical recitation produced no effect ; but the moment the interest of the speaker began to be awakened, the temperature rose. Although the action of the heart was frequently more or less modified, yet this could not account for the rise of temperature, inasmuch as other parts of the body ought, in such a case, to have shared equally in the rise, whereas it was the head that was chiefly, if not solely, affected. Reading or reciting to one's self gave similar results, and often even in a more marked degree.[1] The rise of temperature in this series of experiments was the highest noticed in all the observations given in this article ; a few minutes' recitation producing a greater effect than several hours of deep thought. In conclusion, I would say that, as regards the particular regions of the head in which the elevation of temperature was most marked, it was generally found that the best results were obtained just above the occipital protuberance. This statement applies to all the experiments that have been related. In the last-mentioned series of observations it was not unfrequently found that the temperature of the forehead *fell*, while that of the back of the head *rose ;* but for what reason I have not yet been able to determine.—*New York Medical Journal.*

TWO ATTACKS OF MEASLES WITHIN SIX WEEKS IN THE SAME PATIENT.—Dr. MINOT reported to the Boston Society for Medical Improvement the following case of this : A little boy, three years old, sickened December 21st. An eruption, supposed to be that of measles, appeared on the 25th. The diagnosis was, however, at first a little doubtful, as the eruption was complicated by urticaria for two days. After this time it had a perfectly normal appearance ; moreover, the child had the catarrh, and other general symptoms of measles. A companion who saw him early in the disease, was attacked with measles exactly a fortnight afterwards. A sister of the first patient, four years old, and a young lady visiting in the family, also caught the disease, at intervals of a few weeks, the symptoms and appearances in each being perfectly characteristic. On Feb. 3rd, after a few days' indisposition, the eruption reappeared on the first patient, and went through its course in the usual manner, being accompanied by the catarrh and other symptoms of measles. The interval between the two attacks was six weeks. Singularly enough, of the three individuals who caught the disease from this patient, two, the young lady and the little boy (her brother), had had the disease before.—*Boston Medical and Surgical Journal.*

Medical News.

ROYAL COLLEGE OF SURGEONS, LONDON.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 23rd inst :—

Messrs. Frederick William Wimberly, Donnington, Lincolnshire, of the Middlesex and Galway Hospitals; William Hodgson Pywell, Westminster-bridge-road, of Guy's; Richard Alfred Mowll, Liverpool, of Cork; William Henry Aston, Tupsley, Hereford, of St. Thomas's; Edward Henry Patton, M.D., Montreal, Quebec, of St. Thomas's; M'Gill and Laval; William Julius Mickle, M.D., Toronto, Gwelph, Canada, of St. Thomas's and Toronto; Richard Samuel, Llanelly, Carmarthen, of St. Bartholomew's; Bennet May, Birmingham, of the Birmingham School; William Henry Hubert, Markyate-street, Herts, of St. George's; Roderick Joseph Gilhooley, Dublin, of the Dublin School; Arthur Francis Greenhill, Barnes, of St. George's; Alfred Hollis, L.S.A., Yarmouth, Isle of Wight, of the Middlesex; Joseph Henry Moore, Scarborough, of the Hull School; William Douglas, Belfast, of Edinburgh; Eldred Noble Smith, Hertford, of St. Mary's; David Hamilton, M.D.Edin., Gloucester-street, N.W., of Edinburgh ; John Neville Colley Davies-Colley, M.A., Cantab., Whitefriars, Chester, of Guy's; Henry Horne Balles, Otago, New Zealand, of University College; and Ridley Thomas Hilder, Woking, Surrey, of Guy's.

It is stated that four candidates failed to acquit themselves to the satisfaction of the Court, and were consequently referred to their studies for six months.

HUMAN ANATOMY AND PHYSIOLOGY.—The Professor of Anatomy commenced his Course of Lectures on Tuesday, January 28th, at 1 p.m., at the New Museums; they will be continued on Tuesdays, Thursdays, and Saturdays at the same hour. These Lectures are intended for students of natural science, and students preparing for the special examination for B.A., as well as for medical students. The Anatomical, Demonstrations will be continued by the Professor and Demonstrator of Anatomy on Mondays, Wednesdays, and Fridays, at 6 p.m., in the old Anatomical School, commencing on the 29th. The Demonstrations of minute anatomy will be continued by

1 It is almost needless to say that, in all these experiments, changes of position, or any other disturbing cause, were carefully avoided.

2 With delicate thermo-electric apparatus it is impossible to estimate accurately the thermometric values of the variations observed ; the most that can be done is to make an approximation.

1 The success of these experiments must depend, in a great measure upon individual peculiarity ; and with many persons they would doubtless fail. *Real emotion* must be awakened to produce the rise of temperature. Where this condition of the mind existed, out of more than a hundred observations, I have never known a failure.

the Professor on alternate Mondays at 7 p.m., in the old Anatomical Museum, commencing on Monday February 3rd, and the instruction in minute anatomy will also be continued by Mr. Gedge on Saturdays at 11 a.m.

METROPOLITAN POOR-LAW MEDICAL OFFICERS' ASSOCIATION.—We have been requested to give notice that a quarterly meeting of the above Association will be held at the Ship Hotel, Charing-cross, on Friday, the 31st inst., at 7.30 P.M., when various subjects of interest to Poor-law Medical Officers will be brought forward for discussion. Among them the provision of medicines, &c., by the Guardians, under Section 69 of the Metropolitan Poor Act, 1867, the appointment of Dispensers to Workhouse Infirmaries, and special dietaries for all classes of inmates. Reference will also be made to the large amount of "desk" work imposed upon Medical Officers, and a remedy suggested. Important correspondence with the Poor-law Board, will also be laid before the meeting. Medical officers who have not yet joined the ranks of the Association, and all persons interested in the welfare of the sick poor and of the medical service, are invited to attend. We need scarcely urge those who have time to support by their presence this Association.

HEALTH OF THE NAVY.—The annual returns relating to the health of the navy present a favourable account for the financial year 1866-7. Notwithstanding the prevalence of epidemics on almost every station, the ratio of cases entered on the sick list (1264·8 per 1000 of force), of invaliding (28·7), and of mortality (10·4) were the lowest that have occurred in the 11 years embraced in the returns. The ratios for the ironclads were 1191·8, 23·8 and 4·5, the ratio of cases of sickness being slightly above that of the preceding year, owing to one or two of the vessels being newly commissioned, and consequently furnishing a number of trifling cases of disease. The highest ratio was in the gun vessels, which, from their light draught of water, are often employed near shore on foreign stations, and consequently in localities of a pestilential character. The ratio of mortality was highest in China. There was a great decrease in the death-rate on the West Coast of Africa as compared with the previous year. On the home station there were 155 deaths in a force averaging 23,080; Mediterranean, 35 in 5380; North America and West Indies, 69 in 5295; Brazil, 11 in 1215; Pacific, 21 in 2565; West Coast of Africa, 37 in 1635; East Indies and Cape, 23 in 1550; China 94 in 3515; Australia, 17 in 980; irregular force, 63 in 5060. The beneficial influence of the Contagious Diseases Act is beginning to be more or less felt at the various seaports; but the Act of 1864 was defective in some important points of detail, and the more efficient Act of 1866 did not come into operation until October of that year. To illustrate the effect of these measures in checking disease a table has been compiled showing, in regard to the head-quarters of the Royal Marine division at Plymouth, with a strength ranging between 1500 and 1800, the number of cases of primary syphilis treated in the Marine Infirmary or the Naval Hospital. In the last six months under the old law they were 130 per 1000 of mean force; in 1865 they were 105 per 1000 in the first six months, and 102 in the second; in 1866, 62 per 1000 and 60 per 1000; in the first six months of 1867 only 49 per 1000. Considering that the accommodation for carrying into effect the provisions of the Act have been much short of the necessities of the place, these returns speak strongly for the efficiency of the Act, and for the importance of largely extending the scope of legislation in this direction. Dr. Mackay expresses his earnest hope that the time is not far distant when every large city and seaport in the kingdom will be brought within the sphere of its operation.

M. F. GAVIN, M.D., L.R.C.S.I., Assistant-Oculist, City Hospital, has been appointed Assistant-Physician to out-patients, City Hospital, Boston, U.S.

NOTICES TO CORRESPONDENTS.

Contributions should be LEGIBLY written, on one side of the paper *only*.

Proofs ought in all cases to be corrected and returned without delay.

Proofs reaching authors on or before Friday morning, are expected to be returned to the Editor, at the office, before five P.M., on Friday afternoon.

Proofs reaching authors on Friday evening or Saturday morning *must* be returned to the office by two A.M. on Saturday, which is an early closing day.

Duplicate proofs are sent to authors, in order that they may correct and return one copy, and keep the other for private use.

Mr. HALL, St. John-street, E.C.—There are many different qualities of Court Plaster. A solution of isinglass with a little tincture of benzoin brushed over silk stretched on a frame, is the most common article. Transparent Court Plaster is made of oiled silk. The finest article is prepared on gold-beater's skin. The following useful formula is given by Dr. Paris:—"Gum benzoin ½ oz. rectified spirit 6 oz., dissolve. In a separate vessel dissolve 1 oz. of isinglass in as little water as possible. Strain each solution, mix them, decant the clear portion, and apply it warm with a camel-hair brush."

Dr. WEST, Gt. Malvern.—Friendly hints are at all times acceptable. We hope to publish shortly some further contributions on "Skin Diseases."

A. COX, Esq., Preston.—Merely specimens.

Dr. L. R.—Eminently satisfactory.

W. S. RUSSELL, Esq., Accrington, is thanked for the flattering compliment he paid to the conductors of the journal.

AN OLD SUBSCRIBER, Hoxton, will find his question answered in our last week's journal. Applications for the return of unsuccessful essays should be made to the person to whom they were addressed.

A WELL-WISHER.—If the certificate obtained in 1864, be one recognized by the General Medical Council, it will pass both the College of Surgeons and Apothecaries' Hall, otherwise it will be useless for these two latter bodies. Your question is rather obscure, or it would be answered more fully.

Dr. CAREY's interesting letter shall appear in our next.

Dr. BURSLEM.—The translation of the French Journal of Practical Medicine was discontinued in January, 1866, from some "hitch" in the copyright.

M. B.—Most satisfactory.

Mr. T.—The back volumes of the journal from 1851, are awaiting your messenger at our London office.

The following papers are unavoidably held over:—Anatomical Notes, by A. Macalister, L.R.C.S. Notes of a Case of a Tumour of the Neck, by J. S. Vessey, M.D. Phthisis Pulmonalis, by R. J. Kinkead, L.M.T.C.D., &c. Case of General Paralysis, by W. G. Smith, M.B., &c. Summary of Science, by C. H. Tichborne; and the continuation of the Foreign Medical Literature. The report of the Surgical Society Meeting, held on the 17th, has been received, and will appear in our next.

Communications with enclosures have been received from W. S. Russell, Esq., Accrington; W. A. Cox, Esq., Bath; Mr. P. Matthews, 77, Welbeck-street, W.; W. Jones, Esq., Kuabon; W. Hall, Esq., Clerkenwell; T. Greaves, Esq., Mount Bellew Bridge; J. R. Tuke, Esq., Brighton; D. David, Esq., Cowes; Dr. Harris, Brighton; J. Carter, Esq., Bedford; C. H. Collins, Esq., Chew Magna; G. C. Cockcroft, Esq., Hurworth; Dr. Leigh, Arnold, Notts; Dr. Edwards Crisp, Chelsea; W. Hunter, Esq., Aberdeen; Mr. Johnson, London; Dr. Burt, Ely-place, London; Mr. Turner, London; Dr. W. H. NOTICE TO ADVERTISERS.

The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales, and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

Seven lines and under	£0	3s.	6d.
Per line afterwards	0	0s.	6d.
One-quarter page	1	0s.	0d.
Half ,,	1	15s.	0d.
One ,,	3	0s.	0d.

The average of words per line is twelve.

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

☞ Advertisements for Insertion in this Journal must be at the OFFICE, on SATURDAY, by THREE o'Clock.

The Medical Press & Circular.

Dr. LETHEBY'S

FIRST LECTURE ON FOOD.

VARIETIES OF FOOD—THEIR CHEMICAL COMPOSITION AND NUTRITIVE VALUE.

(Continued from page 87.)

Maize or *Indian Corn* is one of the most extensively used grains in the world. It enters largely into the food of the inhabitants of America, Italy, Corsica, Spain, the south of France, and the Danubian Principalities. Since the famine in Ireland, it has there also become a common article of diet, especially when potatoes are dear; but its flavour is harsh and peculiar, and nothing but a scarcity of more agreeable food reconciles us to its use. The young grain called *cob*, is, however, more palatable, and forms, when boiled in milk, an American luxury, which takes the place of green peas.

The farina is peculiar when examined under the microscope, and will thus serve to recognise it.

Although the meal is rich in nitrogenous matter and fat, it does not make good bread. It is, therefore, either cooked by baking it into cakes, or by stirring it into boiling water, or boiling milk, as in the case of oatmeal, and thus making a sort of hasty-pudding, or thick porridge. This is the method of using it in Ireland, and it is flavoured with salt, or butter, or treacle. The favourite mess called *corn-lob* by the creoles of British Hinduras, is prepared with milk in the same way. Indian meal, mixed with maple sugar, and baked into cakes, formed, at one time, the chief article of diet of the almost extinct Delaware Indians.

When deprived of its gluten, and harsh flavour, by means of a weak solution of caustic soda, and then dried, it forms the expensive food called *Oswega* or *corn flour*, which is now largely used for puddings.

Lastly, it is often mixed with wheaten-flour and baked into bread, but its harsh taste is never completely covered.

The grain is said to cause disease when eaten for a long time, and without other meal—the symptoms being a scaly eruption upon the hands, great prostration of the vital powers, and death after a year or so with extreme emaciation. These effects have been frequently observed among the peasants of Italy, who use the meal as their chief food, but I am not aware of any such effects having been seen in Ireland, where it is often the only article of diet.

The nutritive power of Indian meal is very high, and, considering its price, it is almost, if not altogether, the cheapest food for the poor. Calculated according to the physiological wants of the system, a week's diet for an adult will only cost about 10½d., and excepting split-peas, which are of doubtful digestibility, there is nothing approaching it for economy.

Rice is the principal food of Eastern and southern nations. It is extensively cultivated in India, China, South America, and the southern countries of Europe; and it gives nourishment to not less than a hundred millions of persons. In this country, however, it is rarely employed, except as an adjunct to other foods. Now and then, in times of scarcity, it is used in the place of potatoes. Perhaps 50 per cent. of our labouring classes use it in this manner. It is imported into this country in a decorticated or cleaned condition, but when it has the husk upon it, it is called *paddy*. The kinds which are most esteemed in this country are Carolina and Patna; but according to Dr. Watson there are many Indian varieties which are nearly equal to the American. The proportion of gluten in it is only about 6·3 per cent., and it rarely exceeds 7. It is, in fact, one of the least nitrogenous of all the cereals, and cannot be made into bread, unless it is mixed with wheaten-flour, as is the custom in Paris, in making the best white bread. The proportion of nitrogenous to carbonaceous matter is as 1 to 12·7, or nearly twice the amount in wheat. It is, therefore a good adjunct to highly plastic foods, as ox-liver, poultry veal, and fish; with all of which it goes well, especially in the savoury form of *curry*. Boiled with milk also, and dressed with egg, as rice pudding, it forms a substantial meal; but in no country is it eaten alone.

The *Millets*, called also *Dhurra or Dhoora*, are another kind of grain, and are derived from many species of plants, as *sorghum*, *penicellaria*, *panicum*, &c. Like rice, they are extensively cultivated in India, Egypt, and the interior of Africa, where they are important articles of diet. They are a little more nutritious than rice: for they contain, on an average, about 9 per cent. of nitrogenous matter, with

74 of starch and sugar, 2·6 of fat, and 2·3 of mineral matter. We have no experience of their nutritive properties in this country, except in feeding birds; but in India the grains are ground whole and made into bread.

The last of the grains of any importance is *Quinoa*, a species of *chenopodium*. It is hardly known in this country, although it is extensively cultivated, and consumed on the high table-lands of Chili and Peru. Mr. Johnston has described it, and he says there are two varieties of it—the sweet and bitter—both of which grow at an elevation of 13,000 feet above the level of the sea, where barley and rye refuse to ripen. It is very nutritious, and approaches oatmeal in its chemical composition, the amount of gluten being about 19 per cent., the starch and sugar 60 per cent., and the fat 5.

The next class of farinaceous foods are the *pulses*, as *peas*, *beans*, and *lentils* of this country, and the *dholls* and *grains* of India. They are grown and eaten in all parts of the world, and are everywhere regarded as very nutritious when they can be digested. Nothing, however, but the most prolonged cooking will serve to help in this particular. As will be seen by reference to the tables, where the composition of peas, the type of all of them, is given, they are rich in nitrogenous matter, for peas and beans contain about 23 per cent., and lentils about 25; but the carbonaceous constituents amount to only 59 per cent., or 1 to 2½. They are therefore, when eaten, invariably associated with fat. In India, the favourite pea *(cajanus Indicus)* is rubbed with oil before it is cooked. In Yucatan, and throughout the whole of Central America, where black beans, called *frijoles*, are extensively used as food, they are well boiled in water, and eaten with pepper, salt, and pork. In this country, butter with peas, and fat bacon with beans, are inseparable companions. Lastly, revalenta or ground lentils with cocoa, which contains over 50 per cent. of fat, are mixed in a well-known fancy preparation. The nitrogenous matter of the pulses is not of the nature of gluten, but is more like casein, or the cheesy matter of milk, and it was named by Braconnot, its discoverer, *Legumine*.

Other farinaceous foods, of little importance to us, are the meal of the *edible chesnut*, which is largely used by the peasants of Lombardy; the *Manioc* and *Lotsa meal*, which, Dr. Livingstone says, are the chief vegetable foods of the natives of some parts of South Africa; perhaps, also, the *horse-chesnut* and the *acorn* might be added to the list, for there is hope of their being easily freed from the bitter principle which now renders them useless.

And lastly, of this class of foods are the *starches* and *arrow-roots*, which are so largely imported or prepared in this country. They are *Bermuda*, *Jamaica*, or *West Indian arrowroot*, from *maranta arundinacea*; *East Indian arrow-root*, from various species of *curcuma*; *Tous-les-mois*, from *canna*; *Brazilian arrow-root*, from *jatropha manihot*; which, when dried and partially cooked on hot plates, makes *tapioca*; and which, when baked in its whole condition, forms *cassava* bread; *sago* and *sago-meal*, from the fruit of various species of *sagus*; *Tahiti arrowroot*, from a *tacca*; *Portland arrowroot*, from the tubers of an *arum*; and *English arrowroot*, from *potatoes*. All these are obtained in the same way—namely, by crushing, or bruising, or rasping the root or other substance containing them, and after diffusing through water, allowing the starch or fæculoid matter to deposit; it is then collected on a cloth and dried. In this country, starches are obtained by soaking the grain in an alkaline liquor, which dissolves the gluten, and then crushing between mills, straining to keep back the husk and cellulose, and then washing with water, and allowing the starch to subside. By this method of manufacture a quantity of gluten is obtained, which can be set free from the alkali by an acid, and collected for food.

All the starches and arrows are known by their microscopic characters, and although they have the same chemical composition and nutritive value, yet they are very different in their digestibility, for the true arrowroots of the West Indies, as Bermuda and Jamaica, will often remain on the stomach of an invalid when the others will be rejected.

They contain no nitrogen, or but a trace of it, and therefore have no nitrogenous value, but they are useful for their carbonaceous properties; and they are best cooked by stirring them into boiling water or boiling milk, and then simmering for a minute or so.

The next class of vegetable foods are those which contain much water, and which may be called *succulent vegetable foods*, of which the *potato* is the most important.

Brought to us from America in the seventeenth century, as a rarity, by Sir Walter Raleigh, it has gradually become an almost universal article of diet; for its advantages are so numerous that it will ever be a favourite food. It is, for example, easily cultivated, easily kept, easily cooked, and easily digested; besides which it requires but little flavouring matter, and never wearies the palate. It is therefore used in times of plenty by all classes of persons, and is often eaten in quantities that approach very nearly to the rice allowance of a hungry Hindoo. In Ireland, says Dr. Edward Smith, when the season arrives and potatoes are plentiful, as much as 3½ lbs. are consumed three times in a day by an adult. This, indeed, is the regular allowance, and an Irishman finds no difficulty in consuming his rations of 10½ lbs. of potatoes daily. In England, the farm labourer consumes, on an average, hardly as much in a week. In Anglesea, however, potatoes are eaten twice a day, and the consumption is about 16½ lbs. per adult weekly; and in Scotland the average allowance is 15 lbs. per head weekly.

The nutritive value of the potato is not great, for, in the first place, it contains only about 25 per cent. of solid matter, and of this hardly 2·1 is nitrogenous. Potatoes are also deficient of fat, and therefore they require admixture with nourishing materials. They go well with meat and fish, and are considerably helped with a little dripping or butter; but the great adjunct is milk. In Ireland, potatoes and buttermilk are the principal diet, even in times of plenty.

Considering the cheapness of potatoes, they are a most economical food. At the price of a half-penny a pound, as is set down in table No. 4, it costs but two shillings and threepence a-week to provide the carbon and nitrogen required by an adult; but when potatoes are cultivated upon cottage ground, by wife and children, as is the practice almost everywhere, as much as seven pounds can be easily obtained for a penny, and then the weekly diet would be rather less than eightpence. At this price no vegetable food can compete with it.

Potatoes are best cooked in their skins, for the waste is then only about three per cent., or half an ounce in a pound; whereas, if they are peeled first, it is not less than 14 per cent., or from two to three ounces in a pound. The mealy varieties are more digestible than the close and waxy; in fact, when they are in this state, as is the case with new potatoes, and potatoes late in the season, which have begun to grow, they are best cooked by stewing them.

All succulent vegetables are endowed with anti-scorbutic powers, but potatoes are especially renowned for this property. As far back as the year 1781, Sir Gilbert Blane, in his work on the "Diseases of the Fleet," alluded to the beneficial action of the potato in scurvy, and from that time to the present, its salutary powers have been repeatedly observed. The late Dr. Baly remarked in his inquiries into the diseases of prisoners, that wherever potatoes were used, scurvy was unknown; and it is the almost universal practice now to carry potatoes, fresh or preserved, in all ocean-going vessels, with the view of preventing scurvy.

Other succulent vegetables in common use, as *turnips*, *parsnips*, *carrots*, *artichokes*, *onions*, *leeks*, *cauliflower*, *cabbages*, and *greens*, have, among themselves, nearly the same nutritive value, but they are all much less nutritious than the potato, as will be seen by reference to the Table No. 3; in fact, they do not contain more than from 9 to 17 per cent. of solid matter, and of this only about 1·2 is nitrogenous. They are chiefly valuable for their anti-

scorbutic properties, and for their quality of flavouring insipid food, and diluting strong ones.

Banana and *bread-fruit* are also valuable esculent foods, and are largely used in the tropics. The former contains about 27 per cent. of solid matter, of nearly the same nutritive value as rice. About 6½ lbs. of the fresh fruit, or 2 lbs. of the dry meal, with a quarter of a pound of salt meat or fish, is a common allowance for a labourer. The *bread-fruit* is largely eaten by the natives of the Indian Archipelago, and of the Islands of the South-Sea. There are several varieties of it which come into season at different times. It is very juicy, containing about 80 per cent. of water, and is generally gathered before it is ripe, when the starch is in a mealy condition, and has not undergone change into sugar. The fresh fruit is cooked, by peeling it, wrapping it in leaves, and baking it between hot stones. It then tastes like sweet bread ; but much of the ripe fruit is preserved, by peeling it, cutting it into slices, and packing it very closely in pits in the ground, made water-tight, and lined with banana leaves. After a while it undergoes a sort of fermentation, or, as we should call it from the smell, putrefaction, and the fruit settles into a mass of the consistence of soft cheese. When it is required for use, it is well kneaded, wrapped in leaves, and baked, like the fresh fruit, between hot stones.

Lastly, I may state that ripe fruits, as *apples*, *pears*, *peaches*, *pine-apples*, *oranges*, &c., are not of much nutritive value, for they rarely contain above 13 per cent. of solid matter, and this is of no more value than so much rice, but they have agreeable flavours, and serve the purpose of anti-scorbutic drinks.

Marine Algæ.—Everywhere along our coasts there is abundance of comparatively nutritious food, which may, by a little management, be made palatable. I allude to our *sea-weeds ;* and this Society has distinguished itself by its efforts to utilize this stock of now almost profitless food. Judging from the analysis of Dr. Davy, and Dr. Apjohn, of Dublin, it would seem that when in a moderately dry condition sea-weeds contain from 18 to 26 per cent. of water ; and that the nitrogenous constituents amount to from 9½ to 15 per cent., while the starchy matter and sugar average about 66 per cent. These results place sea-weed among the most nutritious of vegetable substances ; in fact they are richer in nitrogenous matter than oatmeal or Indian corn.

The varieties of sea-weed at present used are the following :—

Porphyra laciniata and *vulgaris*, called *laver* in England, *stoke* in Ireland, and *slouk* in Scotland.

Chondrus crispus, called *carrageen* or *Irish moss*, and also *pearl-moss.*

Laminaria digitata, known as *sea girdle* in England, *tangle* in Scotland, and *red-ware* in the Orkneys ; and *laminaria saccharina alaria esculenta* or *bladder-lock*, called also hen-ware and honey-ware by the Scotch.

Ulva latissima or *green laver.—Rhodomenia palmata*, or dulse of Scotland.—These, with many others, are eaten by the coast inhabitants of this country and the Continent. In some parts of Scotland and Ireland they form a considerable portion of the diet of the poor.

To prepare them for food, they should first be steeped in water to remove saline matter ; and in some cases a little carbonate of soda added to the water will remove the bitterness. They are then stewed in water or milk until they are tender and mucilaginous ; and they are best flavoured with pepper and vinegar. Under the name of *marine sauce*, the lavers were once a luxury in London.

As to the last of the vegetable foods—namely, the *fungi* or *mushrooms*—I have but little to say ; for although the edible varieties are highly nutritious, yet they can never become an important article of diet. Most of them are employed at the present time as flavouring agents ; and among these are the common mushroom for ketchup, the *morel* for gravies, and the truffle for turkeys and the livers of geese *(Pâté de foie gras)*.

Sugar and *Treacle.*—Both of these are very generally consumed on account of their flavouring and fattening qualities. Dr. Edward Smith found that 98 per cent. of indoor operatives partook of sugar—to the extent of 7½ ozs. per adult, weekly. 96 per cent. of Scotch labourers use it, and 80 per cent. of Irish. In Wales, also, it is commonly used to an average extent of 6 ozs. per adult weekly ; but there is a marked difference in the rate of consumption in the northern and southern portions of the country. In North Wales, for example, the average amount per head is 11¼ oz. ; whereas, in South Wales it is only 3 ozs. The principal use of it is to sweeten tea.

Treacle has more flavour than sugar, and it is also cheaper. It is, therefore, more largely employed ; and that description of it properly called *molasses*, which is the draining from the raw or unrefined sugar—treacle being the drainings from refined sugar, is preferred on account of its stronger flavour, and is most usually sold for treacle. They go well with all descriptions of farinaceous food, as porridge, pudding, dumpling and bread.

Sugar contains from 4 to 10 per cent. of moisture, and treacle about 23. The rest is carbonaceous matter, without nitrogen. They are, therefore, heat-producing and fattening agents, and their power. in these respects, is about the same as with starch. Whether they can produce disease when used in excess is a matter of doubt ; but Dr. Richardson declares that they cause blindness by creating opacity of the lens *(cataract).*

Animal Foods.—First on the list of these is *milk*, a liquid which contains all the elements of food required by the very young, and is, therefore, often regarded as the type or standard of food.

In some countries, as Switzerland, it is the chief diet of the peasantry ; and everywhere, if easily obtained, it is largely consumed. 76 per cent. of the labouring classes of England make use of it ; 83 per cent. take it as buttermilk ; and 53 per cent. as skimmed milk. In Wales, the average consumption of it by farm labourers is 4¼ pints per adult, weekly. South Wales averaging only 3 pints, while in North Wales it is 7½. In Scotland the consumption among the labouring classes is still larger, for it amounts to 6¼ pints per head weekly, and in Ireland it reaches 6¾ pints. Those who take least of it are the poor in-door operatives of London ; the weavers of Spitalfield, for example, use only about 7·6 oz. per head weekly, and those of Bethnal-Green only a fraction above 1½ ozs. per head. When examined under the microscope, milk is found to consist of myriads of little globules of butter floating in a clear liquid. On standing for a few hours the oily particles rise to the surface and form of cream, the proportion of which is the test of its quality. Milk is heavier than water in the proportion of from 1030 or 1032 to 1000. Asses milk is the lightest, for its gravity is only about 1019 ; then comes human milk, 1020 ; and, lastly, goat and ewes' milk, which is the heaviest of all, from 1035 to 1042.

The quality of milk varies with the breed of the cow, the nature of its food, and the time of milking, for afternoon milk is always richer than morning, and the last drawn than the first. Taking, however, the average of a large number of samples, it may be said that cows' milk contains 14 per cent. of solid matter, 4·1 of which are casein, 5·2 sugar, 3·9 butter, and 0·0 saline matter. The relations of the nitrogenous to the carbonaceous is 1 to 2·2 ; but as fat is 2½ times more powerful than starch, the relation may be said to be as 1 to 3·6.

When milk is heated to the boiling temperature, the casein is coagulated to some extent ; and if the milk has stood before it is heated, so that the cream may rise, the coagulum includes the cream, and makes the so-called Devonshire or *clotted cream.*

Acids also coagulate the casein, and produce a curd, as in the making of cheese and curds and whey.

Cream is rich in butter, as will be seen by reference to Table No. 3. It contains 34 per cent. of solid matter, 26·7 of which are butter, and its gravity is about 1013.

Skim-milk is the milk from which the cream has been

removed. It contains only about half as much butter as new milk, and its gravity is about 1037. In all other respects it is similar to new milk.

Buttermilk is the residue of the milk or cream from which the butter has been removed by churning. It is still poorer in fat than skim-milk, containing, in fact, only about half as much. Unless it is very fresh, it is generally a little acid, and frequently the acidity has gone so far as to set the milk into a kind of jelly.

The *whey* of milk is the opalescent liquor from which the curd has been removed in making cheese. Although not highly nutritious, it still holds a little casein in solution, as well as the sugar and saline matter of the milk. It is rarely used as food by the poor, but is given to pigs. In Switzerland, however, it is considered to have medicinal virtues, especially for the cure of chronic disorders of the abdominal organs, and the treatment, which is somewhat fashionable, goes by the name of *cure de petit lait.* There is a popular notion, also, that the whey of milk is sudorific, and hence we have our *wine whey, cream of tartar whey, alum whey, tamarand whey,* &c., when the milk has been curdled by these several substances.

Cheese is the coagulated product of milk, obtained by the addition of rennet or a little vinegar. When cream is coagulated it makes *cream cheese*, which will hardly bear keeping, but must be eaten fresh. It contains about half its weight of butter, and a fifth of its weight only of curd.

When cream is added to new milk, and the mixture is curdled, it forms very rich cheese, as *double Gloucester* and *Stilton.*

When new milk alone is used the cheese is less rich, but still of high quality, as *Cheddar.*

When an eighth or a tenth of the cream has been taken off, it produces the quality of cheese which is most sought after, as single Gloucester, Chester, American, &c.

And when all the cream has been removed, and the skim-milk is curdled, it forms the poor cheese of Holland, Friesland, Suffolk, Somersetshire, and South Wales.

At first every variety of cheese is soft and comparatively tasteless, but by keeping they undergo change, and develop their flavours, when they are said to be ripe.

Analyses of two of the most important of them are shown on Table No. 3, and it will be noticed that they contain from 56 to 64 per cent. of solid matter, about half of which is curd. In skim-milk cheese, the curd amounts to 44·8 per cent., and the fat to only 3·6 ; whereas, in Cheddar, the curd is only 28·4 per cent., and the fat 31·1. In nutritive power, therefore, especially in nitrogenous matter, cheese ranks high, and is a valuable article of diet ; but there is a limit to its digestibility, and hence it cannot be taken in large quantity. Considering its price also, it is hardly so profitable as many other foods ; although, where good skim-milk cheese can be purchased at from 2½d. to 3d. a pound it forms, in small quantities at a time, a good adjunct to bread.

(To be continued.)

LECTURES ON VENEREAL DISEASES

DELIVERED IN

DR. STEEVENS' HOSPITAL.

LECTURE I.

By ROBERT McDONNELL, M.D., F.R.S.,

ONE OF THE SURGEONS TO STEEVENS' HOSPITAL.

(Continued from page 89.)

B.—Is it true that the syphilitic sore cannot, as a rule, be inoculated on the bearer ?

Upon this subject the evidence of various experimentalists is tolerably clear.

Ricord says inoculation with the virus of a syphilitic sore upon a person who already bears upon him such a sore is either without result or it produces a sore *like* a simple chancre. This is, indeed, the foundation of Ricord's dogma, that a person can (as a rule) have syphilis only once.

In 1855, Clerc announced that it was not possible to reinoculate the syphilitic sore on the bearer.

In 1856, Henry Lee made experiments on the subject in the Lock Hospital, London, and concluded "that the indurated chancre was not capable of being inoculated upon a patient whose system was already syphilised, in the proper acceptation of the term."

Fournier inoculated 100 patients from their own syphilitic sores, but only twice produced sores like the parent sores. Puche, Poisson, Nadau, have arrived at a similar conclusion—viz., "that the indurated chancre is not autoinoculable more than twice out of 100 times."

Rollet and Laryoenne differ a little from this. They say, not more than 6 times out of 100.

From this testimony we may conclude that, as a rule, the syphilitic sore cannot be inoculated upon the bearer.

It is undisputed that the simple sore may be produced again and again.

C.—Is the syphilitic sore abortible, that is, can we cut short the progress of the disease, and prevent the occurrence of constitutional disease by cutting out the syphilitic sore, or destroying it by escharotics ?

In answer to this question, we have the following evidence :—

J. L. Petit, at the commencement of his practice, used to excise indurated chancres on the prepuce. He finally renounced this operation as one which was found ineffectual in preventing secondary syphilis.

Diday has not succeeded in preventing constitutional syphilis by the destruction of the chancre by chloride of zinc and other caustics, even as early as from three days to twenty-four hours after the sore became apparent.

Henry Lee's opinion on the subject is very decided. He says :—

"In the treatment of syphilitic infection cauterization is of no avail, as far as the prevention of constitutional symptoms is concerned.

"The period of incubation which has elapsed before the disease manifests itself forbids the idea that the poison can then be destroyed by the application of caustic to any particular part.

"Infecting sores that have been destroyed on the very day of their appearance have subsequently continued to spread, and have produced their natural consequence. Even if the infecting sore be cut out, the infection of the patient's system will not thereby be prevented."

The testimony brought before the Venereal Committee has induced them to conclude that "the application of local agents for the purpose of destroying the hard sore is useless."

Ricord practises cauterization at the first, but he admits that once the sore is recognisable by its hard base as a syphilitic chancre, the abortive method has no value. Follin justly observes that no conclusion can be drawn from destruction of a sore at a time when it cannot be determined whether it is a simple or a syphilitic venereal sore. If, after its destruction, the patient escapes without constitutional symptoms, it may be inferred that the sore was from the first non-infecting.

It appears, therefore, that after it is recognisable as a syphilitic sore, it is not abortible.

To excise it or cauterize it is only to lock the stable-door after the horse is stolen.

Among the causes which have involved the study of syphilis in doubt and darkness must be reckoned the tendency which it has to form hybrids with other maladies. In its later forms syphilis may be seen masked and modified by scrofula, rheumatism, scurvy, gout. We know that the vaccine virus and that of syphilis may be put into the soil together, the tares with the wheat, and it is probable that venereal poisons themselves may in like manner become mixed, and thus producing a compound infection give rise to complications of symptoms almost impossible to disentangle.

The "chancre mixte" of Rollet, is, indeed, supposed to arise from the compound virus of the simple and syphilitic sore: it does not, evidently, constitute a new disease, but it is important to recognise it, as it gives a satisfactory explanation of a number of apparently exceptional or contradictory facts.

Rollet, of Lyons, and his school, explain by the theory of the "mixed chancre," several phenomena otherwise out of the usual order, as we may say. Thus, a chancre, to all appearance a simple one, is followed by constitutional symptoms. Ah! they say, it was a mixed chancre, in the initial stage, the disease had the character of the simple sore.

A chancre, apparently altogether syphilitic, with hard base, is reinoculated on the bearer, as may occur four or five times in 100. They say it was a mixed chancre. The purely syphilitic part is not reinoculable, but of course the virus of the simple chancre is; and also suppurating bubo following a chancre, which is, to all appearance, a true syphilitic sore—is explained on the "mixed theory."

We must be slow to admit such an hypothesis without well-observed facts to support it; yet, we cannot deny the possibility, nay, the probability, of a compound infection from the co-existence of the two poisons, at the time of impure contact.

Another question of much interest connected with the subject of syphilis, is the unity or duality of the poison—in other words, whether the simple sore and the syphilitic sore arise from one virus, or are due to two distinct poisons. Ricord, theoretically, believes in the unity of the poisons, but I may say that, practically, he is a dualist, for he teaches that the simple chancre may be distinguished from the syphilitic one—that secondary accidents follow the latter only, and for it alone he reserves mercurial treatment. Clerc, Diday, Rollet, Guerin, Lancereaux, and other distinguished names, are found among those who believe that we have to do with two distinct poisons. For my own part, if you ask me to what conclusion I have come upon this subject, I shall answer you by an analogy. I should say that as in natural history, I am a follower of the distinguished Darwin, and believe that the wolf and the dog are probably descended from a common ancestor, although now regarded as a distinct species, so it is possible that the simple and the syphilitic sore may have had, in past times, a common origin, but that the lapse of years and circumstances which have not yet been determined have given to them certain distinct characteristics; so that like the dog and the wolf, the simple and the syphilitic sores may be regarded as specifically distinct.

In short, gentlemen, when we find that the usual characteristics of the syphilitic sore differ so from the *usual* characteristics of the simple sore, that

We see in the former—	*and*	*We see in the latter—*
Almost always a solitary sore;		Very often several sores at the same time;
A hard sore;		A soft sore;
Incubation of some weeks;		No incubation;
Adhesive inflammation;		Suppurative inflammation;
Incapability of inoculation upon the person who has the sore;		Capability of inoculating an indefinite number of times the person who has the sore;
Not to be destroyed by excision or caustics;		Able to be completely destroyed;
Constantly accompanied by indolent, hard bubo;		When accompanied by bubo, suppuration soon following;
Producing in due course secondary symptoms;		Purely local in its effects;
Influenced by so-called specific treatment.		Uninfluenced by specifics.

When we see all this, is it not hard to resist the conclusion that whether arising originally from a common source or not, we have now to do with two distinct morbid principles; that small-pox does not differ more from measles, the dog from the wolf—than the simple venereal sore does from the syphilitic.

You must remember, however, that there are many distinguished authorities, and we may especially mention Melchior Robert, and Langlebert, who still believe in the unity of the chancrous poison; they hold that the virus, the seed, is one and the same in all chancres; that the conditions of the soil make the difference. Their doctrine is, that if the seed falls on uncongenial soil, if the virus affects an individual whose peculiarity of constitution, state of health, or other circumstances, render him inapt for its development, it germinates and springs up, but to be blighted after a few weeks; it produces a local sore, perhaps a suppurating bubo, nothing more. But if it falls on a soil fit for its reception, it strikes root in the hard sore, and flourishes in due time to bear flower and fruit in the secondary and tertiary consequences.

In attempting impartially to decide upon this question of the unity or duality of the syphilitic poison, it appears to me that the evidence derived from the experiments of Wallace, Waller, and others, cannot be got over. Twenty-six times competent observers have been guilty of the outrage on humanity of inoculating healthy persons with syphilitic poison, (an outrage hardly to be justified, it is true, even by the gain to science); in every case where the poison *took* at all, a syphilitic chancre followed—with subsequent constitutional disease.

In twenty-six persons of different ages, sex, strength, constitution, &c., in Dublin, Prague, Lyons, Paris, Wurzburg, not one simple sore with suppurating bubo, and nothing else. Now, knowing what we do about the more usual occurrence of the simple sore, are we to conclude that by a remarkable coincidence, all of the persons infected chanced to be fertile syphilitic soils; or, are we to believe that a syphilitic sore in every virgin soil, produces its like, and that the simple sore is essentially distinct from it? This is our dilemma, and, in the present state of knowledge, I take the latter view.

Original Communications.

ON THE TREATMENT OF DISEASES OF THE SKIN.

By J. L. MILTON.

SURGEON TO ST JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

CHAPTER I.—PAPULÆ.

A. Strophulus—Definition.—An eruption of small, prominent, generally hard, papulæ, varying in colour from a vivid red to white, attended with some itching, and ending, after a few weeks, in branny desquamation, generally seated on the face, but may appear on the neck, arms, shoulders, back of hands, breast, and loins. Peculiarly a disorder of early infantile life. Divisions—1. S. intertinctus or red gum, in which the papulæ are red; 2. S. confertus, or rank red gum or tooth rash, in which the papulæ are paler, but more numerous; 3. S. volaticus, in which the papulæ are red, and grouped in small clusters of from three to ten or twelve; 4. S. albidus, in which the papulæ are hard, small, and whitish, with a red halo; and 5. S. candidus, in which they are white, without a halo.

Strophulus rarely requires active treatment. Sometimes the bowels are a good deal disturbed, there being griping, irregular purging, and symptoms of acidity. In such cases mild doses of antacids and aperients, for instance, a combination of soda and magnesia with a little mercury and chalk, will do good. To this some carminative, like dill water or cinnamon water, may be added. Strophulus is by no means necessarily connected with dentition, but if there be any irritation set up from this cause, it cannot too soon be removed by lancing the gums.

When the surface is dry or chapped, Mr. Wilson recommends the use of an ointment containing half a drachm of liquor plumbi to the ounce (the sparmaceti cerate or ointment of the London Pharmacopœia being both very good vehicles), or an ounce of oxide of zinc ointment, rubbed down with a drachm of spirit of camphor.

A lotion, containing half a drachm of borate of soda, and two drachms of glycerine in three ounces of elder flower waters, may be employed almost *ad libitum* during the day, and at night cold cream, or an ointment containing five minims of chloroform, half a drachm of glycerine, a scruple of calomel, and three drachms of lard, may be smeared on the part. If, however, these remedies are to do good, it is absolutely necessary that the materials employed should be pure, and this is only too often *not* the case. The stuff constantly sold as cold cream, prepared with bladder lard adulterated with lime and salt, is a very different thing from cold cream made by a first-class chemist. I have known two or three applications of what passed for zinc ointment remove the epidermis from the scrotum of a patient suffering under a tender state of that part, almost as effectually as a blister would have done, and yet the irritation of the surface thus denuded has been relieved by the use of the same ointment properly made. Mr. Wilson relates, that having been consulted by a surgeon, he ordered him zinc ointment which the surgeon procured from his own hospital. Mr. Wilson, anxious to know what a hospital's idea of zinc ointment might be, asked to see a specimen, and was favoured with a view of some stuff much more fitted for greasing cart wheels than for applying to the human skin.

This neglect is all the more unpardonable because very simple measures will ensure efficiency. Thoroughly purified lard should be used, and this can only be had by paying a higher price than usual, or by taking the trouble to melt down the flare and strain it through flannel ; the addition of ten grains of gum-benjamin to each ounce will prevent any rancidity. The pure gum or tears should be picked out, broken, and digested in warm lard for forty-eight hours. This mixture is afterwards strained, and then the active ingredient is added. For zinc ointment the oxide is used,[1] and Mr. Wilson prefers the buff-coloured oxide of the pharmacopœia to the white oxide made by combustion. I think, however, that anything to be used for the hands, head, or face cannot be too free from colour, and, as the white oxide can now be had very pure, I decidedly prefer it.

Some writers say ointments are barbarous,[2] and apt to become rancid. But a remedy which promotes the patient's comfort and the cure of the disease most certainly ought not to be called by such a name ; and when it is rancid, either there has been great neglect, or bad materials have been used. I appeal to the experience of the best authorities in these diseases, whether ointments do not agree better than any other applications whatever with many affections of the skin. It is well known that both Mr. Wilson and Mr. Startin have devoted the greatest care to this speciality, and they both employ ointments freely. But the reader has only to use them properly in order to satisfy himself that in eczema, and many other allied affections, they not only exert a most decided action over the disease, but that they form the most defence yet discovered against the irritation which the contact of air with the diseased surface is apt to set up, a point of vast importance in very raw or cold dry weather, preventing, Mr. Wilson thinks, the great oxygenation of the blood, which is apt to occur in inflamed surfaces when exposed to the atmosphere.

B. Lichen—Definition.—An eruption of small, hard, red, conical papules, not followed by ulceration, pustules, vesicles, or discharge, though one or more of these may complicate it in very severe cases, accompanied by heat, tingling, and often violent itching ; each papula becoming covered by a thin, small scale, or having the summit torn off by scratching. Divisions—1. L. simplex, where the eruption is moderately red and scattered over the surface of the body ; 2. L. urticatus, in which the pimples are large, often bear a suspicious resemblance to flea or bug bites, and, on scratching, look like spots of nettle rash ; seen almost exclusively in children and delicate women ; 3. L. tropicus, very small hard, rough papules, generally in clusters, attended with the most violent itching, and mostly seen either in the tropics or in persons who have resided there ; 4. L. planus, (Wilson), in which the papulæ are dull red, flattened, and glazed at the summit ; always associated with constitutional disorders ; 5. L. scrofulosorum (Hebra), in which the papulæ are the size of a millet seed, pale, yellowish, and red, scattered in smallish colours, covered with little scales, and not excoriated ; 6. L. lividus, the same as l. simplex, but the papules are of a purplish colour ; L. pilaris, in which the papules surround the hairs at their base. Both these divisions might, I think, very well be abolished, but Mr. Wilson and Mr. Startin retain them.

In simple lichen, especially when acute, it is not necessary to do more than keep the patient quiet, and give a febrifuge and brisk aperient. Citrate of potass or soda, taken effervescing every hour or two, acts very well in these cases, and now and then it may be requisite to give a mild sedative at bed-time, such as five grains of extract of poppy or lettuce, with a little opium ; or tincture of hyoscyamus, to be taken in camphor mixture, may be prescribed. So soon as convalescence is established, a grain or two of quinine dissolved in a little dilute sulphuric acid[1] can be given two or three times daily.

My business, however, lies principally with the chronic forms of lichen; and of these, lichen agrius and lichen urticatus are selected as typical divisions, the tropical form being very rarely seen in this country, and the forms mentioned by Hebra and Wilson having been very seldom seen even by them. The remedies, then, for these varieties of lichen may be arranged in the following order, and, provided the leading indications they afford be carefully looked to, the form in which they are given may be left to the taste and judgment of the surgeon.

These remedies are :

1. First a tonic, such as nitric acid, given in some bitter infusion, for two or three weeks. About fifteen minims in an ounce of infusion of quassia, or in a wine-glassful of water with a drachm of some tonic tincture, like calumbo or cinchona, may be taken three times a day, about half-an-hour before meals. When the patient is low and anæmic steel may be given in the form of citrate or tincture instead of nitric acid.[2] Whichever be given, an aperient should always be ordered at the same time.

It is advisable, in some cases, to examine the urine, and should oxalate of lime be found, nitro-muriatic in the same doses may be substituted for nitric acid.

2. Any particular disorder of the health, such as rheumatism, gout, or wasting, for instance, or of a function affecting the health, such as indigestion or inactivity of the liver, should be met by appropriate remedies, as, for instance, iodide of potassium and colchicum, cod-liver oil, afterwards mild doses of mercury, &c.; and I would most strongly recommend any such disturbance being thoroughly set right before the real curative treatment is begun with.

3. Lastly, in all refractory cases, a course of arsenic should be ordered, and as so very much depends upon the way in which it is given, I shall once for all venture to bring forward what I believe to be the conditions essential to success; for if arsenic is to do good, it must be used

1 Bell's formula for preparing the benzoated oxide of zinc ointment, as given in Mr. Wilson's work on Diseases of the Skin, is as follows:—

R. Adipis preparatæ ℥vj. Gum. Benzoin pulv. ℥j., liquefac cum leni calore per horas xxiv. in vaso clauso; dein cola per linteum, et. adde oxyd zinc purif ℥i. misce bene et per linteum exprime.

2 "Greasy applications under any circumstances are barbarous, and often injurious in the treatment of cutaneous disease."—Burgess.

1 The following formula will, I think, be found very useful:—

R. Quinæ disulphatis, gr. xii.
Acidi sulph. dil. ℥iss.
Tinct. cardam. c. ℥ss.
Aquæ cinnam. ad. ℥vi. ♏.
Coch. amp. i. ter quotidie sum.

2 The reader can try the subjoined formula:—

R. Ferri et quinæ cit. ℥i.
Ammon. sesquicarb ℥ij.
Spir. myristecæ ♏.
Syrup simpl. ℥ij.
Aq. ad. ℥vj. ♏.

A table-spoonful in a wine-glassful of water to be mixed with half an ounce of lemon-juice, and drunk effervescing three times a-day.

properly. By this I mean, that whether the plan of prescribing it in small doses at first, and gradually increasing them, or of beginning with large doses and decreasing them, be adopted, the plan, once decided upon, should be regularly and consistently carried out; and if any interruptions to it be thought requisite, they should only be made on really valid grounds, and be as systematic as the rules for taking the medicine. The surgeon may often suspend the use of arsenic with advantage; the suspension of it by the patient without orders can scarcely fail, sooner or later, to retard the cure. If the patient will give up arsenic whenever he is going out to see his friends, or when he has friends coming to see him; when he is away on business or on pleasure, both being, of course, potent reasons for neglecting treatment; when he is tired of medicine, or fancies it may not agree with him; in short, if he will take it in any way but the right way, he had better not take it at all. Properly employed, arsenic is quite as safe a medicine as mercury or antimony—if, indeed, it be not much safer; though some practitioners who give these freely enough, seem to regard arsenic with a special horror; but it is only safe, just as it is only useful, when given in this way.

Perhaps the plan so strongly pressed upon notice by Mr. Hunt, of giving full doses at first and gradually reducing them to such an amount as will maintain a decided action on the system, and of always giving the dose upon a full stomach, is the best; and certainly Mr. Hunt deserves the highest praise for the resolution with which he has sought to force upon the profession a recognition of the value of arsenic. At the same time, it cannot be denied that the opposite system, if carefully worked out, is perfectly safe. It is therefore, perhaps, of little moment which system is adopted, but it is of great moment that it should be steadily adhered to, and that a proper preparation of arsenic should be given.

De Valangin's solution is one of the best formulæ, but the surgeon must remember that there are now two preparations of this name: the original, twelve minims of which are equal to five of Fowler's solution, and that recommended in the British Pharmacopœia, which is of the same strength as Fowler's solution. Ten or twelve minims of the former, or four or five of the latter, may be given three times a-day, either with the food or directly after, but on no account on an empty stomach. If taken with the food it may be mixed with anything the patient is drinking, as tea, beer, wine, &c.; if taken after food, with a wineglassful of water.

I have no faith in arsenic in the shape of pills, or indeed in any solid form whatever. Besides, many persons cannot take pills, especially in great numbers, and they are not at all suited for children. The only remaining preparations of arsenic of which I have any great experience, are Fowler's solution and Donovan's. Till I tried the solution of the chloride of arsenic I thought Fowler's the best of all, and even now I would not undertake to prove that De Valangin's is better, though I believe it to be so. Should the reader prefer Fowler's solution, he will find it, despite the changes in opinion called into life by fashion, a most valuable remedy. But I would strongly recommend the omission of the compound spirit of lavender, the objection to which I pointed out years ago. The faint mawkish taste it gives to each dose is far more repulsive to many patients than anything either bitter or sour. I am glad to find that both Wilson and Hardy sanction the expulsion of such a nauseous and useless ingredient. Donovan's solution proved useless in my hands. I never saw any harm arise from using it, but it would seem that others have. Mr. Hunt says, "if there be one medicine more dangerous than another, it is the villanous compound of arsenic, iodine, and mercury, known by the name of Donovan's solution." I share in this view so far as to believe that it is undesirable to give either iodine or mercury along with arsenic; an occasional dose of either can do harm, especially if the arsenic be suspended, but while it is being taken the less its action is interfered with by such powerful medicines the better.

The dose and the mode of taking the arsenic having been decided upon, the next consideration is the length of time it requires to be taken, and respecting this, I believe there is but one opinion among those who have most carefully studied the subject, and that is, that it must be continued till the disease is thoroughly subdued, if not altogether cured. Mr. Hunt looks upon a pricking sensation in the conjunctiva as a sign that the curative action of the arsenic has been set up, and he considers that, if just enough of the mineral be given to keep up this action, we shall get all the good we can from the remedy with the least amount of disturbance. In some persons arsenic brings on a dirty brown staining of the skin, with desquamation, where it is hidden from light, and Mr. Hunt finds that a dose large enough to keep up this discolouration, and yet not large enough to make the conjunctiva tender, will ensure the curative action of the medicine just as effectually as the largest amount. I believe myself that one of the best guides we can have is the action of the bowels. When the arsenic is making the stools a little more fluid and frequent than usual, it is doing all it can do, and it is rarely necessary to make any change in the mode of administering it. I have repeatedly found that after a short course of three full doses daily, the daily use of five minims of Fowler's solution would cure the relics of an obstinate skin disease, and at the same time keep the bowels in perfect order; for arsenic, properly given, instead of exasperating, soothes an irritated state of the bowels.

With some persons, arsenic, in very small doses, will bring on nausea, irritability of the stomach, sickness, purging, and a general feeling of being very much out of sorts. Perhaps the best method of meeting these disagreeable symptoms is the following:—The arsenic is interrupted for one day, a mild pill is given the night previous, and a dose of magnesia in the morning; the patient may lie in bed, if practicable, during the early part of the day, and take only very light food, the arsenic is then resumed the day after, and taken the last thing before going to bed. If it still produce sickness and irritation, the dose must be reduced again, for there is always a point at which arsenic will do good, without inducing disorder of the health; in fact, the dose which just stops short of this is precisely the dose that effects the greatest amount of benefit. Some surgeons, in case of great sickness and irritation, add opium, hydrocyanic acid, &c., in order to diminish these, but my opinion is quite opposed to the practice. I have always found that arsenic answers best when its action is not masked.

I may here remark, that in many thousand cases of disease of the skin, I have never seen an instance of such remarkable intolerance of arsenic as Mr. Hunt speaks of. The smallest quantity I have known to disagree with a grown up person, was about two minims of Fowler's solution daily. I had under my care a woman suffering from erythema, who complained so much of disturbance in her head, and excitement, from the use of Valangin's solution in very small doses, that the quantity was gradually lowered to two minims a day, but in this instance, I had every reason to believe, that the patient was not very anxious to be cured.

Patients often get tired of the mere repetition of medicine, however well it may be agreeing with them, and then they or their friends propose giving it up for a little while, and trying change of air, &c.; I believe this to be, in almost every instance, a mistake, to which the surgeon should not yield: once a hold gained over the disease, it ought never to be relaxed; patients suffering under complaints for which arsenic is required, generally derive much less benefit from change of air than they expect, certainly far less than compensates for interrupting a course of arsenic, and having to go through the whole process again; and travelling, unless it can be continued for a very long time indeed, and under very favourable circumstances, will not cure a bad case of skin disease.

Mr. Wilson recommends[1] for the constitutional treatment of lichen, the mildest aperients, followed by bitters

1 Diseases of the Skin. Sixth Edition. P. 202.

and mineral acids, by chalybeates and quinine, or by quinine and iron. In chronic cases, he has much faith in arsenic. For lichen planus he gives the ferro-arsenical mixture. His local treatment consists of juniper tar soap, tepid bathing, emulsion of bitter almonds, with hydrocyanic acid, bichloride of mercury and spirit of wine, and lotions of carbolic acid. His great remedy for the itching, and one which he considers a most valuable agent in lichen urticatus, is a lotion of pyroligneus oil of juniper, and spirit of wine, an ounce of each in six ounces of water. In obstinate lichen circumscriptus, he recommends gentle friction with ointment of ammonio-chloride, or nitric oxide of mercury, or the ung. picis liquidæ. For lichen planus, lotion of the bichloride of mercury or the solution of the pentasulphide of calcium. Mr. Wilson thinks daily bathing of great value.

Mr. Startin bleeds for this affection. For the lichen sparsus of authors, he uses a lotion of bichloride of mercury and creosote water to allay the itching. In cases of lichen pilaris, accompanied by asthenic look and languid circulation, he prescribes the persulphate of iron in infusion of quassia, and ointment of white precipitate of mercury and levigated sulphur. For the feverishness of lichen agrius, he gives purgatives and diaphoretic diluents, with a very strictly regulated diet, after these a quarter of a grain of iodine, with twenty minims of liquor potassæ, and ten of colchicum wine, three times a day, with creosote ointment and a very free use of baths. He then gives calomel and opium at bed time, to which succeed bichloride of mercury, in doses of one-sixth of a grain, and lotions of bisulphuret and bichloride of mercury applied warm. Finally, come aperient chalybeates and lotions of borate of soda and glycerin. For the livid form (lichen lividus), Mr. Startin uses acid chalybeates, hot air baths, and sulphur fumigations. Lichen tropicus, which he considers to be the same complaint as pellagra, is not marked out by him as requiring any particular line of treatment.

Hospital Reports.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

Dr. FLEMING'S Surgical Clinique.

V.—HERNIA AND HYDROCELE—DISTRIBUTION OF TRUSSES.

SINCE the last report, isolated cases of hernia and hydrocele presented at hospital, some in out-patients, others in patients admitted into hospital for different diseases. Amongst them there was a case of "inguinal hernia" on the right side, accompanied with well-marked "encysted hydrocele of the cord" on the left side, in a healthy boy, aged 8 years. This boy had been wearing a truss from infancy for this hernia, which, from the account given, had been inguino-scrotal, and the usual truss mark was visible. The signs of the hernia had now disappeared; there was no "pointing," no bulging of the integuments at or near the internal ring in the erect posture, or no impulse communicated on coughing; in fact, the cure of the hernia had been accomplished, which Dr. Fleming remarked might be considered the rule in such class of cases at that early period of life. He recommended, however, that a light protective truss should yet be worn. With respect to the "hydrocele of the cord," he observed that it had peculiarities, to which he wished to direct attention. Its diagnostic features were clear, and each was commented upon. The translucency of the hydrocele was specially obvious—it was remarkably tense and defined in outline—the cord was most distinct above and below the tumour, and the testicle was equally distinct. Dr. Fleming did yet think that the tumour descended much lower into the scrotum than usual in such cases, and that it was very near the testicle, the latter organ, however, being as distinct in the most unequivocally marked "scrotal hernia." The tapping of the hydrocele was contemplated, and after two days' interval, the boy again presented himself at hospital for that purpose. Whether from previous rough manipulation in testing the several diagnostic marks of the tumour, or from some other cause, the aspect of the case was now so completely altered that non-interference, as regarded tapping, was deemed more prudent. The translucency of the tumour was unsatisfactory—its outline was no longer well-defined—and its size was decidedly influenced by compression, when it almost completely, as if solved down into a general fulness, which was accompanied with a peculiar rustling sensation, communicated to the fingers as they passed along the chord towards the internal ring. In fact, the impression on the mind of Dr. Fleming was, that either the "encysted" was converted into the "diffused hydrocele of the chord" or that symptoms of inguinal hernia were probably superinduced by some disarrangement of the vaginal or funicular portion of the chord. The occasional use of a local embrocation was directed, and a double truss was suggested as the most suitable expedient under the altered circumstances of the case, if they continued. The importance of attention to the varying features, which the more rare forms of hernia often presented, was hence inculcated.

A case of double femoral hernia in the male, was next brought under notice, and although each hernia was large and of long standing, no application had ever been made for a truss, or indeed for any advice respecting the nature of the tumours, until distressing dyspeptic symptoms occurred. One of these herniæ had tilted over Poupart's ligament—the other formed a somewhat oval tumour beneath the ligament. The requisite form of double truss suitable in such case was directed.

Another case of "inguinal hernia," which, in Dr. Fleming's opinion, strongly simulated femoral hernia, presented itself in a man, aged beyond 50 years, who had worn a badly-fitting truss for a lengthened period. In shape it resembled a femoral hernia: it did not protrude under Poupart's ligament, but rather through an abnormal splitting or separation of the fibres of that ligament, as it passed towards its insertion into the pubis, and so, did not pass through the external abdominal ring, but along the outside of the chord, into the scrotum. The body of the sac was spherical, and there was not the slightest disposition in it to ascend over Poupart's ligament, though the hernia was larger than an ordinary orange.

Dr. Fleming marked the importance of attention to those varieties in the direction and course of many cases of inguinal hernia. They merited careful investigation, in order not to prejudge too rapidly as to their absolute nature.

"Hydroceles of the hernial sac," were next alluded to. They were a very rare form of hernial complication. Dr. Fleming could only bring to his recollection two or three such cases since his appointment to the hospital, now more than fifteen years back, and the subjects of those cases were adults in early life, who had large scrotal herniæ of long standing, not fully reducible, and herniæ which were of that obscure and rare variety presenting in adult life, termed "congenital inguinal hernia."

The essential features of "hydroceles of the hernial sac," were detailed and illustrated by several drawings, special allusion having been made to a most instructive case which had lately been under observation in hospital, and which, having terminated fatally, afforded an opportunity of examining a most interesting pathological specimen exhibiting this special hydrocele. The details of this case were brought under the notice of the Pathological Society, and will be published in its proceedings.

Dr. Fleming stated that he was disposed to classify those "hydroceles of hernial sacs" as "vaginal hydroceles of the testicle" are classified — namely, into the acute and chronic forms, the acute, by no means rare of occurrence, as exemplified in the sacs of strangulated hernia; the chronic very rare, and then met with in those large scro-

tal herniæ so common amongst the working classes. To assist in the differential diagnosis of such cases, the immeasurable value of percussion was enforced and its effects were demonstrated on scrotal herniæ, and contrasted with the effects on ordinary hydroceles, with few restrictions, heretofore exemplified.

MEATH HOSPITAL AND COUNTY OF DUBLIN INFIRMARY.

Cases under the care of Mr. PORTER.

I.—A LARGE INTRACTABLE INDOLENT ULCER OF THE LEG—AMPUTATION.

We are indebted to the courtesy of Mr. Porter for an opportunity of being present at an operation which he performed on Wednesday last. The patient, a man aged 42 years, had suffered from a very large ulcer of his right leg for four years. The diseased condition occupied two-thirds of the circumference of the limb, and extended upwards from the ankles to the junction of the middle and lower thirds. The sore constantly poured out a copious fetid discharge, and had baffled all attempts to heal it.

The operation was performed about a hand's-breadth below the knee. Mr. Porter rapidly drew the knife across the front of the limb from the edge of the tibia internally in a lunated direction, until the point of the instrument reached the posterior margin of the fibula, when he transfixed the leg and quickly cut his posterior flap from the calf. Then, having cleared the bones by carrying round the knife, and also passing it between the tibia and fibula, he cut the bones in a rounded manner with Butcher's saw. He then proceeded to secure the vessels by acupressure, but found this very difficult, owing to their having retracted considerably, and also from the oblique way in which they were cut. He applied ligatures to all but the peroneal, which had retracted so much that it caused a good deal of trouble and delay in the dressing of the stump. He succeeded, however, in arresting it by passing an acupressure needle deeply under it, and looping the artery over with wire. Finally, he brought the flaps together by means of wire sutures, and a very accurately fitting line of incision and well-formed stump resulted.

II.—A LARGE PHOSPHATIC CALCULUS IN THE BLADDER OF A FEMALE—LITHOTRITY.

A woman, aged 45 years, has just left the hospital cured of a large urinary calculus after four crushings. She had suffered for one year and nine months from frequent micturition, and at times dreadful pain in the region of her bladder. Her urine was constantly turbid, and occasionally bloody. She had been treated in the country for uterine disease before she came under Mr. Porter's care, and the stone had never been suspected until it was discovered by Dr. Evory Kennedy, who sent the case to the Meath Hospital. She was in other respects a healthy woman, and she had a very large urethra. On the 26th of December, Mr. Porter measured the stone with Sir H. Thompson's flat-bladed lithotrite, the diameter in which he caught it, was one inch and a quarter. He subsequently on four occasions, or *sittings*, crushed the calculus with the same instrument, and the debris amounting to 615 grains in weight were passed, with the exception of one large fragment which Mr. Porter extracted with the lithotrite. He injected the bladder at each operation, except the last. She left the hospital well on the 26th inst. Mr. Porter pointed out to the class the great advantages of lithotrity, stating that had he cut the stone out through her vagina, a fistula might have resulted; or if, on the other hand, he had dilated her urethra by mechanical means she might never again have been able properly to retain her urine. The operation by which he freed her of the stone, shattered it to fragments, it was washed out by the natural flow of urine, and left her in a sound condition. The sittings were almost painless, so that she never required chloroform, and she was only confined to bed for two days after each operation. During the entire management of the case Mr. Porter mentioned that he had freely given the patient opium, both by the mouth and also in the form of suppository.

The examination of the debris showed the calculus to consist of a mixture of triple phosphate, and phosphate of lime, but not in the proportions which yield the "fusible calculus." The nucleus was lithate.

ST. GEORGE'S HOSPITAL.

A YEAR'S SURGICAL PRACTICE.

(Continued from page 92.)

In continuing our account of the year's surgical practice as related by Mr. Ring, we come next to diseases of the organs of motion. First, we are told of 136 cases of disease of bone and periosteum. In 42 of these there was necrosis. In one, the lower jaw and first cervical vertebra were both effected. There was hemiplegia. The boy improved under treatment by iodide of potassium and sarsaparilla. A trial was made of equal parts of sulphuric acid and water to dissolve dead bone, and the plan was in several cases successful.

There were 30 cases of caries and disease of the ends of joints. In three of them, the tarsus was affected, and in one the ankle-joint was implicated, and amputation of the leg performed. In four cases of caries of the bones of the foot, Syme's amputation through the ankle-joint was resorted to with good results. In one case of disease of the os calcis, Mr. Tatum removed the bone by means of a T-shaped incision on the outer side of the foot.

Diseased bone and scrofulous matter were, in two cases, removed with the gouge. In one of these the dorsalis pedis artery was divided; and so thickened were the tissues around it, that it was found impossible to command the vessel with a ligature; by acupressure, however, the bleeding was readily arrested. This patient had more bone removed at a subsequent operation, and was discharged with a useful foot.

Two cases of excision were performed—one of the shoulder, and one of the wrist, after Mr. Lister's method. In the first case, the right shoulder had become painful and swollen four months before admission, and abscesses had formed; the joint was much enlarged, and gave great pain, especially at night. On the inner side of the arm there was an open sinus. Dead bone could be felt with a probe. Excision of the head of the humerus was performed by means of a semilunar incision on the outer side of the joint: the glenoïd cavity was healthy. A good deal of fever followed the operation; but in three months recovery took place, with partial ankylosis; the wound was not quite healed when the patient was discharged. The excision of th wrist was performed for strumous disease, implicating all the bones of the carpus. Mr. Lister's method of operating was the one adopted. An incision was made on either side of the wrist, through which the whole of the carpus, with the carpal extremities of the metacarpus, radius, and ulna, was removed. None of the tendons, except those attached to the bones removed, were interfered with. The wounds were adjusted with silver sutures, and the limb was placed on a splint. For a few days the tendon of the extensor secundi intermedii pollicis was exposed, but it soon became covered with healthy granulations: passive motion was commenced on the third day after the operation. The wounds healed rapidly; the patient could soon move his fingers. He attended as out-patient for about a month afterwards.

Forty-two cases of *diseases of the spine* were admitted, of which five were lateral curvature, and the remainder angular.

In twelve of the cases of angular curvature, the disease

existed in some part of the dorsal region ; and in nine cases in the lumbar. The dorsal and lumbar vertebræ together were implicated in three instances. In one of these there was lateral curvature as well, with a distorted chest, &c., and the patient was discharged as incurable.

Eleven cases were complicated with psoas abscess, and two with lumbar ; whilst, in several instances, pain on percussing the spine, with or without abscess, was the only indication of the disease ; there being no perceptible inequality of the vertebræ. In six cases the abscess was opened, and in one it was allowed to burst. In two instances the abscess had burst, and was discharging when the patients were admitted. One patient was discharged at his own request, and one died of phthisis and amyloid disease.

In two instances, the cervical vertebræ were affected : in one there was paraplegia, in the other partial hemiplegia. The lower cervical and upper dorsal vertebræ were implicated in one case. A spinal apparatus was applied.

In one of the five cases of lateral curvature, there was some loss of power in the lower extremities, with inability to straighten them from contraction of the hamstring tendons : the left hand was also somewhat contracted : symptoms of phthisis supervened.

Four cases of *tumours* connected with bone were admitted. One was an exostosis of the femur, situated in the most usual place for these growths—the inner side of the lower end of the femur. It caused great inconvenience in walking, and was therefore removed. There were similar growths of smaller size on the fingers and opposite femur. The second was a myeloid tumour of the lower jaw. It had been growing for ten months, and had attained the size of a walnut. It was removed with bone forceps. The third was a case of considerable interest, inasmuch as there was some doubt as to its nature. A girl, aged 16, was admitted with the history, that four years ago she had been kicked in the left leg. A month after this, a swelling appeared at the spot where she was struck, and it increased gradually ever since. Blisters had been applied without effect. On the outer side of the left leg was a large fluctuating swelling, covered with discoloured skin ; its margin was defined by a rough, hard elevation, feeling like a ridge of bone. The swelling was tapped, and a small amount of purulent fluid drawn off. In about a month the abscess burst, and a large amount of foul pus escaped. A sinus was now left in the limb, which showed no disposition to heal. The patient's health remained good, and it was proposed at some future time to remove the mass, which could be felt to be attached to the fibula. In March, 1867, the tumour, with the portion of the fibula to which it was connected, was removed. The bone was hollowed out and expanded ; the tumour was found to consist of a soft, semi-gelatinous mass, which, under the microscope, was seen to consist mainly of oat-shaped cells, nucleated and nucleolated. The fourth was a case of malignant disease. Last year the mass attached to the scapula had been removed, the whole bone being dissected out, except the acromion process. When re-admitted, there was a large, tense, hard swelling filling up the whole of the right axilla. She complained of pain in the chest, and occasional shortness of breath. It continued to enlarge, and the patient was seized with dyspnœa several times, and died. An enormous mass of encephaloid disease was found in the axilla, with deposits of a similar nature in the lungs. A large abscess was found in the right pleural cavity ; the left contained air, and about a pint of clear fluid. The posterior part of the deltoid, the lower part of the trapezius, the serratus magnus, and the rhomboidei were completely wasted, the muscular substance being replaced by a dense fibrous membrane. The acromion process was somewhat depressed, and the head of the humerus rested against it and the acromial end of the clavicle. The arch was completed in front by the coracoid process and coraco-acromial ligament. The head of the humerus was surrounded by a dense capsule, and a perfect joint was thus formed.

Ten cases of *periostitis* came under notice. Two only were acute. In one of these the left leg had become painful and swollen without assignable cause. A free incision was made and pus evacuated. The patient left at his own request when the wound had nearly healed. The other case proved fatal from pyæmia. It occurred in a boy aged 16. He stated that six weeks previously he had had a blow on the right knee, but he took no notice of it. About five weeks after, he had pain in the chest, and on the day following, cramp and pain in the right knee. When admitted he was in a feverish state ; the knee was slightly red and swollen. Warm Goulard lotion and laudanum were applied. Two days after, he had vomiting; and on the following day the knee was swollen, and acutely tender and painful. The skin over the inner and front part of the knee and upper part of the leg was of a rose tint. Tongue coated and dry; respiration hurried; expression anxious; lower chain of inguinal glands enlarged, but not painful. Next day he was delirious. The superficial veins over lower part of the thigh were well-marked. He was ordered brandy and an effervescing saline, with an anodyne draught at night. The limb was enveloped in a linseed-meal poultice. This treatment was pursued for two more days, when fluctuation appeared over the tibia, and an incision was made down to the bone ; pus freely escaped, and the periosteum was found separated from the tibia. Symptoms of pyæmia now set in, and six days later he died.

Out of one hundred and forty-two cases of *disease of the joints* thirty-seven were cases of *synovitis*, for the most part chronic, the result of previous injury, except four, which were due to gonorrhœa, and three to rheumatism. One was a case of rheumatoid arthritis of the knee.

Seventeen cases of *abscess in joints* were admitted, affecting the shoulder, elbow, wrist, sacro-iliac, knee, and ankle-joints. In two instances the shoulder-joint was implicated. In both ankylosis resulted. In one of these the abscess was of large size, and was situated beneath the right pectoral muscles. It was opened, and a drainage-tube inserted. A great deal of fever followed, which reduced the patient to a very low state. The elbow-joint was implicated in three instances; in two of these death resulted from pyæmia. [They were included in the report on this disease in The Medical Press and Circular of Jan. 8th.] In three instances the sacro-iliac synchondrosis was affected. In one of these the abscess appeared over the joint itself; in the other it extended down the back of the left thigh to the popliteal space. In both cases the abscess was allowed to discharge itself spontaneously, and the sinuses healed. In the remaining case the abscess was situated in the groin, and did not heal. Abscess of the knee-joint occurred in seven cases ; in four of these amputation of the thigh was performed, two were attacked with phagedæna, and one died of pyæmia (also included in report above cited). In one instance excision was performed, the wound never quite healed, and the patient was readmitted, and died of albuminuria and amyloid disease. In one case the joint was much swollen, and the presence of pus was determined by means of a grooved needle. The patient was discharged at his own request.

Nineteen cases of *ankylosed joints* were admitted. A large proportion of these were admitted on account of the unfavourable position in which the joint had become fixed. A more useful position was in numerous instances obtained by force, employed under chloroform, or by the subcutaneous division of tendons. In one case of ankylosis of the elbow excision was performed. The result was unfavourable ; and amputation was peformed at a later date.

Disease of the hip presented forty-nine examples, amongst which are to be found instances of the disease at its earliest commencement and latest stages. The treatment adopted was the same as that thus summed up in a former report :—"The early cases are of especial interest in showing the admirable effect of rest-treatment. The plan usually adopted is to place the patient under chloroform, and carefully to adapt a well-padded long splint down the outer side of the thigh, making slight extension by means

of a perinæal strap. The effect of this is almost immediately to relieve pain ; and children who were admitted in a state of great febrile excitement, and suffering intense pain—so much so that they could not bear to be moved or lie in any position but that so characteristic of acute hip-joint disease—are found in the course of a day or two to be comparatively comfortable, with a cool skin and clean tongue, and suffering little or no pain. They are kept on their backs in this position till all appearance of mischief has subsided, and are then allowed to go about on crutches with a well-fitted leather splint. Another mode of applying extension was by means of a weight, attached to the foot by means of a string, which ran through a pulley at the foot of the bed" (St. George's Hos. Rep., vol. 2.)

Forty-nine cases of *disease of the bursæ* were admitted, and of these forty-three were of the bursa patellæ. In many of these suppuration had occurred, and an incision, with poultices, was required. In more numerous instances, however, rest and cold lotions averted the danger of the formation of pus. Chronic cases were treated by the application of blisters, or the tincture of iodine. In one case the bursa had solidified, and was removed.

Four cases of inflammation of the bursa over the olecranon were admitted. In one of them suppuration had occurred. One case is entered as an enlarged bursa in the ham. The swelling subsided under the influence of rest and a cold lotion.

The cases of *thecal abscess* were mostly confined to the flexors of the fingers or thumb. Early and free incisions, with the removal of any useless parts, constituted the local treatment. Three deaths occurred from pyæmia, whilst several were complicated with diffuse inflammation of the forearm, or inflamed absorbents.

Nineteen cases of *contracted tendons* occurred. These were for the most part treated by the subcutaneous division of the affected tendons, and the subsequent straightening of the foot by means of a Scarpa's shoe.

Two cases of *ganglion* in the popliteal space were treated by repeated blisterings and the occasional withdrawal of their contents by a fine trocar and canula. One patient was admitted with six toes on each foot. He found them an inconvenience in walking, and had one from each foot removed.

(To be continued.)

Reviews.

NUTRITION THE BASIS OF THE TREATMENT OF DISEASE : The Introductory Address at the Opening of the Medical Session of University College, London. October 1, 1867. By GRAILY HEWITT, M.D.Lond., F.R.C.P., &c. London. 1867.

THE following extract will give a fair sample of the nature and extent of the nutrition to which Dr. Hewitt refers. We quote from pp. 16 and 17:—

"It is not, however, simply in obviating the effects of acute disease that the remedial power of good nutrition possesses such forcible claims on our attention. Disease has a beginning. That prevention is better than cure is a maxim old as the hills. A very large number of deaths are due to diseases which originate in defective nutrition. Consumption, in its many forms and disguises, appears to be essentially connected with want of food. That there are other influences also concerned in the production of this class of diseases, it would not, perhaps, be altogether correct to deny, but it is very certain that the nutritive method of treatment has, under otherwise ordinary favourable circumstances, a most marvellous power in arresting its onward progress and, unless the disease has absolutely destroyed some considerable portion of a vital organ, in curing this fell disease. That the same plan of treatment applied at an earlier period would prevent its occurrence altogether is to be expected. During certain periods in the life of the individual the growth is excessively rapid ; in youth and childhood the framework of the body is incessantly increasing in size, not only so, but the changes in the tissues proceed with a vehemence and activity which are no longer witnessed when maturity has been reached. The remark might seem almost superfluous, that, to maintain this growth, food in large quantities will be required. It is not surprising to find that the most disastrous results follow whenever this fundamental principle is neglected. It is impossible to estimate, with any degree of accuracy, the number of deaths really due in this way to defective nutrition, for a vast number of them do not appear as such in the Registrar-General's Report ; the body does not always and at once succumb, but it is weakened, and its power of resistance diminished, and it falls an easy prey to one or other of the malign influences perpetually on the watch to attack it."

"THE BRITISH PHARMACOPŒIA, 1867," CONSIDERED. Being the Inaugural Address for the Thirteenth Session of the School of Medicine of the Catholic University of Ireland. By S. M. MACSWINEY, M.D., Dean of Medical Faculty, &c. Dublin. 1867.

DR. MACSWINEY'S lecture opens with a well-merited tribute to the public and private merits of the late Mr. Andrew Ellis, and, this done, he proceeds to offer criticisms on the new Pharmacopœia. Unlike most criticisms of that book, Dr. MacSwiney's is not only not abusive, but really gives a succinct and fair account of Pharmacopœias in general, and traces the legitimate descent of the present book, from the crude attempts of earlier times. He thinks (as we think) that the edition of 1867 is a considerable improvement on that of 1864 ; and he draws a very useful comparison between the new French Codex and the new British Pharmacopœia. This is a very useful kind of introductory lecture.

A LECTURE GIVEN AT THE MEATH HOSPITAL, ON THE OCCASION OF THE OPENING OF THE SESSION. November 4, 1867. By MAURICE HENRY COLLIS, M.D.Dub., F.R.C.S.I., Surgeon to the Hospital, &c. Dublin. 1867.

MR. COLLIS has struck out for himself a comparatively new and independent line in his Introductory Lecture, and instead of occupying an hour in giving advice which few are likely to follow, or in enunciating truisms, of which teachers and pupils are alike weary and impatient, he has undertaken a task of much usefulness, and has furnished us with a really interesting and well-written account of the Meath Hospital, which is now 115 years old, and which has had various changes of locality, fortune, and management, during that lengthened period.

If Medical Officers of other hospitals in Dublin, were to follow Mr. Collis's example, and give histories of their respective hospitals in their introductory lectures in 1868, we should at once have what is much wanted, a collection of historical records concerning the Dublin Hospitals, which could be afterwards revised and edited in one volume by some competent person. We have read Mr. Collis's lecture with much pleasure, and we can readily commend it to the notice and perusal of our readers.

HANDBOOK OF THE SPHYGMOGRAPH : Being a Guide to its Use in Clinical Research. To which is appended a Lecture delivered at the Royal College of Physicians on the 29th of March, 1867, on the Mode and Duration of the Contraction of the Heart in Health and Disease. By J. BURDON SANDERSON, M.D., F.R.S., Physician to the Hospital for Consumption, Assistant-Physician to Middlesex Hospital, and Joint Lecturer on Physiology in the Middlesex Hospital Medical College. London: Hardwicke. Pp. 83.

THE small book before us is the second English publication on the use of the sphygmograph which has appeared during the last two years ; a fact which speaks well for the activity of the cultivation of the graphical method of research, and, at the same time, indicates that the sphygmograph is gaining general recognition as an instrument of medical investigation. The precision which it gives in able hands to the study of the peculiarities of the pulse, the assistance which it promises to afford as an aid to prognosis, and as an indicator of the effects of remedies in fevers, render Marey's invention a very valuable addition to the resources of the physician. The use of the instrument requires, however, a certain amount of skill, and in order to obtain an accurate record of the pulse movements, no small care must be exercised in its adjustment. Wolff particularly dwells on these points, in his able work, and we can heartily recommend all readers of German to study the "Charakteristik des Arterien Pulses."

"The Handbook" has been written, as Dr. Sanderson tells

us. to help those using the sphygmograph "to overcome those preliminary difficulties which are apt to be encountered in the application of any new method of research." Of course a description of the instrument is given at length in the first chapter, and the familiar illustrations of Marey are to be found in the frontispiece. As our author recommends some modifications in the instrument, it is to be regretted that new woodcuts were not introduced, to assist the reader in comprehending the suggestions in the text. The japanned wings of Marey's instrument are recommended to be removed, in order to allow of the adjustment of a rectangular block of brass to the under surface of that end of the instrument which is placed near the wrist. By the under surface of this block, the sphygmograph "rests on the tendon of the *flexor longus pollicis*, and the space between that tendon and the spine of the radius." The forearm is supported and its movements controlled by the use of Mr. Berkeley Hill's pad, and the instrument is fixed by an elastic band which passes over the brass block referred to. The author's plan of varying the pressure is next described, and we quote it at length for the benefit of our readers, although we must confess that it is somewhat difficult to understand, as no diagrams (except those alluded to above) are given to assist the reader.

"Having found by experience, that it is not expedient to work with any less pressure on the artery than 100 grammes, and that the greatest distance between the wooden lever and the spring which the construction of the instrument admits of, is 11-20ths of an inch, it became my object to tighten the screw, P,[1] to such a degree that the force required to bend the spring back to the distance indicated should be equal to the weight of 100 grammes. For this purpose I fix the sphygmograph in a vice, and by means of a counterpoised loop of wire attached to the end of the beam of a balance, the opposite pan of which contains a weight of 100 grammes, exert the required pressure on the spring. This done, I turn the screw, P, until the upper surface of the spring is exactly 11-20ths of an inch from the lever. Having arrived at this point, the permanent adjustment is complete, and the screw must not be touched. I then place 300 grammes instead of 100 in the pan, and ascertain the distance between the surface of the spring and the lever under this increased pressure; and finally, by repeating the experiment with various weights, I determine the relation between distance and pressure with such accuracy, that by measuring the former the latter can always be known."

The first part of the second chapter is composed of an account of the "terms usually employed in describing the character of the pulse as felt at the wrist." And at the end of the chapter there is an attempt at a classification of the pulse, under the two heads of soft and hard pulses. The only pulse traces which the first three chapters contain are given in illustration of this classification.

The two sections in this chapter which treat of the "arterial movements which constitute the pulse," and the "practical application of results," subjects which it is essential the student should clearly understand, are, we regret to say, anything but clear.

The obscurity arises chiefly from the want of any previous definition of the technical terms employed. The terms "first event" and "second event," &c., are frequently used, and the reader has to turn to the lecture at the end of the volume before he can obtain any definite idea of the author's meaning. Dr. Sanderson has endeavoured to introduce new descriptive terms in speaking of the pulse, but in our opinion he has not succeeded in making the subject clearer by this change. On the contrary, he has introduced a source of some confusion, as the majority of those who apply the sphygmograph to clinical research will be certain to follow the modes of expression used in the standard works of Marey and Wolff. These authors, especially the former, describe the various curves of the pulse-trace, and speak of the ascending line, the summit, and the descending line of each pulsation. The descending line is usually marked by small undulations which are termed secondary waves or curves.

In this method the technical terms refer to a visible representation of the pulse movements, each one of which is, of course, associated in the mind with the idea of a corresponding movement in the artery. The standard being a visible and easily comprehensible one, the mind travels without difficulty from it to the pulse-movements, of which it is the representation. In Dr. Sanderson's method the student has first to fix in his mind the idea of the succession of movements which form each pulsation, and just as the impressions derived from touch are in this case, at best, much less vivid than those derivable from the graphical representation of that which can only be vaguely felt; so the technical language which refers purely to the movements of the artery must always be more difficult to realize, and more troublesome to learn, than that which relates to the pulse-trace.

In a work that aims at being "a grammar of the sphygmograph," to use the author's own phrase, we have a right to expect at least clearness of expression, and the materials necessary to enable the reader to understand the literature of the subject. Any who rely on Dr. Sanderson's "grammar" will, however, be disappointed in this expectation, as no reference is even made to the descriptive terms used by the inventor of the syhygmograph himself, and the very names of others whose writings should be consulted by all who use the instrument are not to be found in the pages of "The Handbook."

A careful definition of the author's own technicalities should, at all events, have been given, and an enumeration of the corresponding terms used by others; the work might then have proved an assistance, instead of a source of difficulty to the student of the literature of the graphical method.

The third chapter is entitled "Notes on Certain Causes and Complications of Disorders of the Circulation," and contains some useful and interesting observations. The remarks on the irregularity of the pulse in mitral disease are especially worthy of consideration, but we fancy our author makes a strange mistake when he says "the *irregularity* met with in mitral disease possesses a character not before noticed by writers, which affords a key both to its cause and the only mode of remedying it. In the irregular pulse of mitral regurgitation the contractions of the heart may be divided into two classes—those which are frequent, short and ineffectual, and those which are long and forcible; and it is found by observation that the former occur during inspiration, the latter during the respiratory pause." Marey, in his remarks on the pulse of mitral regurgitation, refers to this point in a note, and suggests the method in which future observation should be made to determine the exact relation between the respiratory act and the irregularity of the pulse. The rythmical character of the irregularity has, moreover, been long known to practical physicians. Dr. Sanderson must, however, have the credit of offering a very plausible explanation of the causes on which the irregularity depends.

The lecture, which forms the concluding part of the little book, is by far the best chapter in the volume. We need not analyse it here, as our readers are already acquainted with it. It has appeared at length in one of our weekly contemporaries, and in the abstract form in all the others. Had the same care been expended on the other chapters, the result would have been much more useful to the student and creditable to the author.

1 The screw P regulates the inclination of the spring, which presses on the artery, and so adjusts the pressure in the sphygmograph as generally used.

OLD ST. ANDREWS.—A Legend in Forddun's "Scotichronicon" tells us how a Greek monk named Regulus (Scotice, St. Rule), who dwelt at Patræ in Achaia, was warned in a vision one night, about the beginning of the fourth Christian century, to take certain portions of the skeleton of St. Andrew, of which he was custodian, and carry them away to the utmost limit of the western world. Putting the arm, three finger-joints, a tooth, and a knee-cap of the dead apostle into a coffer, he committed himself, in company with some followers, to the sea, and, after much suffering and peril from Mediterranean and Atlantic billows, was wrecked with his treasure almost at the very spot where the Thistle as just recorded went to pieces. The saint and the box were both saved; and the king of the Picts, extending his protection to the guardians of a trust so sacred, conferred upon the strangers the Boar forest, which then occupied the rocky promontory on which the city of St. Andrews now stands, and built for them a church, whose tall square steeple, formed of a masonry that seemed to bid defiance to time and weather, still rises from the graveyard of the ruined Cathedral. This religious settlement at first bore the name Kilrule, but the presence of St. Andrew's bones induced later residents to call it by the name of the apostle who became patron saint of Scotland. The Culdee monastery of the Kirkheugh, which arose, after the days of St. Columbia, on the seaward angle of the hill that overlooks the harbour of St. Andrews, became in time the nucleus of a Roman bishopric, the third in order of foundation on

Scottish soil. But more than all other events that contributed to make St. Andrews the ecclesiastical capital of mediæval Scotland, was the institution there in 1144 of a house of Augustine Friars, whose prior was entitled to wear the ring, mitre, and crozier of a bishop, and to take a place in Parliament above all other prelates of the clergy.—*Marjorie Dudingstone, a Tale of Old St. Andrews.*

PROFESSIONAL EDUCATION.

Of all the subjects that are continually cropping up and *obtaining* ephemeral attention, no one is more important than that of medical education. Yet its unsatisfactory condition remains year after year the bugbear and annoyance alike of teachers and pupils, and the unredressed evil that does more than anything besides to keep the Profession under the thrall of the "Old men of the mountain" it has erected in the corporations, beneath the weight of which we groan. Nevertheless, there is too much disposition to shelve the question. Often have we, as journalists, been told that we do not keep the subject as much in the foreground as we might; but what are we to do? All our volumes, and those of our contemporaries too, prove that medical editors are more ready to discuss education than those whose duty it is to adopt decided action, and for a long time the dead weight of the corporate bodies has produced apathy amongst those to whom the journals look for aid.

In 1858, the Medical Council came into being, armed with authority to grapple with the question. Every year it has met—and talked—and talked. It has done—literally nothing; and here we are, in 1868, no nearer, apparently, to a better system than we were when this corporation was created out of the heterogeneous materials of the older corporations. We have called it before the *corporation of the corporations,* and that phrase well describes its constitution and its weakness. Until we have reformed it we can hope for little.

It is strange, but alas! true, that the metropolis should still be the centre where this evil is most apparent. A conviction of this gave rise to the Medical Teachers' Association in London, from which good things have been hoped, but which will accomplish nothing unless it gets out of the old ruts in which it seems disposed to run.

There was something positively melancholy in a society of gentlemen so influential devoting an evening to the suggestion of various plans to secure an audience to authorized teachers, and this, too, after Mr. SIMON, as president, had delivered an address full of thought, that might have stirred them to something better.

We hear so much of schemes to compel pupils to put in an appearance at the lecture rooms, that it might well be imagined that medical students of the present day exercised all their ingenuity in baffling deans and consuming their days in pot-houses or billiard rooms. But is this so? Are the students all lazy? Are the majority of them incorrigible? Do they regard lectures as a veteran might morning drill? and, if so, is it not possible that authorities and teachers have been playing the martinet with too high a hand? Let us be just, and let lecturers honestly ask themselves if *all* the fault is *always* on the side of the listeners.

Mr. SIMON treated the subject from a very rational point of view. First, he glanced at the examining boards, and the picture he drew of the Royal College of Surgeons of England was as faithful as it is shameful. With him we call on all to think for a moment—"What the Council might have done in the last 25 years, if it had administered its great trust disinterestedly." The utter selfishness of this body, its carelessness of everything but the securing of its own perquisites, the grand position the College might have held, the depth to which it has fallen, are too well known to need a word more. Authority, wealth, influence—it has had all—and what has it done to promote medical science? What has it done to improve medical education, which it has virtually controlled? Echo answers—What? Nor can the London College of Physicians expect anything but censure. It is poor, say its apologists! It may be that it has been poor in cash, but it has been rich in influence and authority. The veneration of age has settled upon it, the traditions of the wise and good should have saved it from the long slumber from which it is now being galvanised. It has had opportunities which will not soon recur, of controlling the whole profession in England, and has meanly squandered them. Its prestige alone, a century ago, would have sufficed to place medical education on a firm and broad basis, upon which we might now have been building. It might have been the great medical university of the United Kingdom, and—it would not. It doffed its gowns, prated dog latin about the dignity of the physician, and handed over the profession to the management of the Apothecaries' Guild. In thus abdicating its functions, it perhaps did well after all; for the Worshipful Company has discharged its duty far better than the poor but proud College.

The Apothecaries' Company has done more to raise the status of medical men, and improve medical education, than all the other English corporations put together. Honour to whom honour is due, and in reference to professional education, there are not two opinions amongst those who have watched its development during the last quarter of a century. If the General Medical Council would evince as much earnestness as the Apothecaries' Society has done to fulfil its duty, we should soon have a reform.

We have dwelt longer than we intended upon this branch of the subject, as we are desirous of recording our conviction that Mr. SIMON only expressed a general feeling when he proceeded to the next and objected to the mass of *Regulations* under which the work of education is conducted. Mr. SIMON would abolish all the petty restrictions that cramp teachers and pupils, and serve no good end. He said, "If I could assume the thorough efficiency and disinterestedness of our examining Boards, I would be well satis-

fied to look to the stringency of the examination as a substitute for all regulations whatever, and would admit to be examined with a view to registration, anyone who had arrived at the age for undertaking civil responsibilities."

Why should we doubt the possibility of such a fair and impartial board being constituted? The University of London has always held this reputation, and no one anticipates anything but fair play from the examiners of the Apothecaries' Society. These boards are independent of the influences which destroy confidence in our Royal Colleges, and they are consequently more trusted.

Licensing bodies ought not to have incompatible functions. If we are to have a multiplicity of examining boards, and there seems little hope of sweeping any of them away, at least, let their examinations not be such transparent shams as to necessitate the issue of a complex code of regulations to prove the candidate has had the opportunity of learning. Test his knowledge, not his means of study. Who does not know that the ablest teacher may waste his energy on inattentive students, whose schedules must be signed, as they are present, in body, at the lecture, though they may be far away in mind; while a diligent student, with only small opportunities, will take the highest place in the class-list of the college, and carry off the honours at the University? We trust then that Mr. SIMON'S words will not pass away unheeded; but they will, unless the profession will speak out and rouse the General Council from its slumber. A radical reform is needed. The present method of education is everywhere pronounced unsatisfactory. Everyone complains that the tree, so carefully tended, pruned, and watered, brings forth no fruit, but no one proposes to hew it down. The time is, however, surely coming for sterner measures. For our part, we proclaim that the axe is ready. Mr. SIMON has taken it up, and looked at it, and even whetted it, but laid it down again. We speak out its use, and call upon some sturdy woodman to lay stroke to stroke till the tree falls.

THE CONTAGIOUS DISEASES' ACT.

IT requires a good deal of courage for the general press to venture on a discussion respecting the prevalence of venereal disease, or the utility of the Act of 1866. Yet we may be sure that so long as discussion is confined to medical journals it will not result in action. It was, therefore, with considerable satisfaction that we read Dr. POLLOCK'S letter in the *Times* last November, and prepared some criticisms upon it, for which, however, we were unable at the time to find space. This was the less to be regretted since the letter in question was a model of good taste. It is at all times a ticklish thing for a medical man to append his name to a communication to the non-professional press. How much more on a subject like this? Dr. POLLOCK, therefore, deserves the warmest compliments for the manner in which he carried out his praiseworthy intention. We are led to revert to this by an appeal made last Friday in the same paper. It is Mr. SKEY who now comes forward, and, if we are not prepared to endorse all he says, we may hope that the subject will receive the attention it deserves. It is pretty well-known that we are not ready to adopt all the squeamish notions of some medical journalists, who are in many things more prudish than is good for professional ethics. We may, therefore, safely leave in their hands the ungrateful task of pointing out the blots in Mr. SKEY'S manner of making his appeal, and devote our own attention to the subject itself. We have before had occasion to speak of Mr. SKEY'S literary performances, and no one will deny that we have done this fearlessly enough. What, then, does he ask in his letter, which we earnestly wish had been half the length? He appeals to the nation on behalf of fallen women, and seems to desire to found an agency more extensive than the association for extending the operation of the Contagious Diseases' Act. That association pleads to the world for hospitals. Mr. SKEY is a member, and an earnest one, of it; but he raises his voice for something more. He pleads for reformatories. So far, we would give him every aid; but he does not stop here. While the association calls for subscriptions, Mr. SKEY makes his "appeal to the funds of the nation." He declares that "justice precedes both private charity and national honour," and as a sort of corollary, of which, however, we scarcely see the necessity, goes on to express his desire "to enlist the sympathy of those who command the exchequer of Great Britain, to obtain for every such victim the option of reformation and of a home, of a pure, moral, and religious atmosphere."

Now, here we pause in doubt whether Mr. SKEY'S idea of the magnitude of the evil has not carried him beyond the bounds of prudence.

The remedy he proposes, if we correctly understand him, should take the form, not only of public acknowledgment, but involves a call on the national purse. Now, here he unites against himself forces of the most dissimilar kind, which are sure to weigh him down. The dreadful people whose political economy would be outraged, the kindly but uninformed, who will not learn, because they think that virtue consists in averting the eye from vice; the bigoted set whose prejudices will be shocked by such proposals to recognize the claims of the outcast; the Pharisees who would not be seen to touch what they consider defiled; the Levites who would pass by on the other side. These, and more than these, will unite to defend the exchequer of Great Britain from Mr. SKEY'S attack, and leave the evil unredressed.

For this reason we think he would have done better to limit his appeal, too, to private contributions, for the toil spent in organising a plan to carry out the view he has propounded would suffice to direct a by no means insignificant stream of British benevolence into the channel where we confess it is so much needed.

Notes on Current Topics.

The Public Health.

IN the fourth week of the year the annual rate of mortality in the large towns was 27 per 1000. In London the rate was only 23, in Edinburgh it was 31, in Dublin 37, in Bristol 27, in Birmingham 24, in Liverpool 32, in Manchester 38, in Salford 28, in Sheffield 26, in Bradford 31, in Leeds 23, in Hull 23, in Newcastle 27, in Glasgow 31. There were 1395 deaths registered in London. This is 321 below the average number of this week, corrected for increase of population. The health of London, therefore, continues very good. The deaths from zymotic diseases were much below the average, being 249 instead of 348. There were 21 deaths from small-pox, 42 from measles, 22 from scarlatina, 5 from diphtheria, 52 from whooping-cough, 31 from fever, 13 from diarrhœa. Of chest diseases

we note 157 deaths from phthisis, 206 from bronchitis, 89 from pneumonia, 66 from disease of the heart. The mortality, relatively low in all divisions, was only 22 in West London.

How to Stamp Out Disease.

We have stamped out the rinderpest. Can we do a similar thing in the diseases that afflict mankind? The uncomfortable sounding suggestion is not ours, but Sir J. Simpson's. That author has just reprinted, as a pamphlet, his "Proposal to stamp out Small-pox and other Contagious Diseases." He tells us that *isolation* will accomplish in small-pox what the pole-axe did for the cattle-plague, and urges the question as one for strict legislative measures. The regulations he proposes comprise—1. The earliest possible notification of the disease after it has broken out. 2. The seclusion of those attacked, at home or in hospital, until all power of infection is passed. 3. Surrounding the sick with nurses and attendants who are known to be protected. 4. Purification of the rooms, clothes, and persons of the sick, and those about them by disinfectants.

By such means as these Sir James Simpson believes we might rid the community not only of small-pox but of other contagious diseases. There are many who will be glad to read and distribute the pamphlet which is published by Messrs. Edmonston and Douglas, of Edinburgh.

The Adulteration of Food and Drugs.

A bill on this subject has been prepared by Mr. Postgate, F.R.C.S., of Birmingham, and placed in the hands of Mr. George Dixon, M.P., to be introduced into Parliament next session. It is entitled "A Bill to amend an Act for Preventing the Adulteration of Food or Drink, 6th August, 1860, 23rd and 24th Vict., cap. 84, and to Prevent the Adulteration of Drugs." The second refers to persons selling adulterated articles. It increases the penalty to £50, and drugs are included with food and drink. The third clause substitutes "shall" for "may," appoint, in Clause 2 of the present act, thereby giving further powers to local authorities, and rendering the appointment of analysts compulsory. The existing act is merely permissive. Clause 6 provides that the analysts shall report quarterly to the local authorities appointing them, the number of articles examined, specifying the nature and kind of adulterations detected. All such reports to be read publicly at the meetings of the local authorities appointing the analyst. Clause 8 provides that any purchaser shall on payment of not more than 5s. be entitled to have any article analysed by the public analyst and receive a certificate of the result of the analysis specifying whether in the opinion of the examiner the article is adulterated, and whether if it be an article of food or drink, it is so adulterated as to be injurious to the health of persons eating or drinking it; such certificate, in the absence of contrary evidence, to be sufficient testimony before a justice, or in any court of justice, of the matters therein certified, and the sum so directed to be paid for the certificate, to be deemed part of the costs. By Clause 9, analysts or inspectors are to report the prevalence of adulterations in food and drink, and drugs, in manufactories in their districts, the objectionable goods to be seized by order of a magistrate. The other provisions of the present act are to remain in force, but drugs are to be included as well as food and drink.

The Medical Club.

The Committee have announced the removal of the club, on the 25th March next, from their present temporary rooms to more central and convenient premises, No. 9, Spring Gardens, S.W.

The new club house is a handsome building, recently erected, and overlooking Trafalgar-square; it will admit of considerable increase in the amount of sleeping accommodation, both as regards the number and size of the bedrooms. In addition to the reading-room and coffee-room, there will be a billiard-room, private dining-room, lavatory, and dressing-room, &c.

The entrance fee for members joining until June 30th is eight guineas, and the annual subscription for those residing in London, four guineas; those resident elsewhere, two guineas. After June 30th, the entrance will be fifteen guineas, and the annual subscription six guineas and three guineas.

Poor-law Doctors.

We beg to direct the attention of our readers to the report, which appears in another column, of the quarterly meeting of the Metropolitan Poor-law Medical Officers' Association, held on the 31st ult. From this, it would appear that we, in common with all the rest of the world, have been labouring under a mistake in supposing that "all" the medicines supplied to the sick poor in receipt of relief, by Guardians in the metropolis, would be paid for on and after the 29th day of September, 1867, out of the Common Poor Fund, as the plain reading of the Act seemed to indicate, the Poor-law Board having ruled that "when a medical officer has contracted with the Guardians to find drugs and medicines, he must continue to do so until his contract has been determined." As nearly all the contracts in question bind medical officers to find the medicines, and as very few of them have been determined since the Act came into operation, it follows that only a small proportion of "all" the medicines is at present paid for out of the fund instituted for this and other cognate purposes. It has been suggested, indeed, that medical officers under contract to find the medicines may apply direct to the dispensers of the Common Poor Fund for re-imbursement, and no doubt such application will be made. But the proper course appears to have been adopted by the Association in directing an appeal to the Poor-law Board to determine the contracts, with the view of carrying into effect the intentions of Parliament. If the Board have this power, they should use it; if they have it not, they should at once apply to Parliament for a supplementary Act. We shall probably return to this subject again shortly, as well as to the other topics discussed at the meeting of this useful and spirited Association.

Dr. John Davy, F.R.S.

We regret to announce the death of the venerable brother of Sir Humphrey Davy, which took place at Ambleside on the 24th ult. Dr. John Davy was born at Penzance in 1790, and was consequently full of years as well as of honour. He graduated at the University of Edinburgh in 1814, and was, for some time, an army surgeon. He attained a reputation as a chemist and physiologist, and was a voluminous writer, though, to the general public, he was perhaps best known as the author of the life of his still more distinguished brother.

Baby Farming.

THE system of nursing which has grown up, and upon the recent revelations of which we have several times commented, is, no doubt, of a most dangerous tendency, and deserving of full investigation. Some of our contemporaries seem to have met with shocking instances of inhumanity and crime. There is, however, no need to rush to extremes, and condemn every woman who takes a child to nurse, or adopts one, as a murderess. We have met with cases which, to an outsider, might look suspicious, but which were as straightforward as possible. We know of at least one case in which an advertisement was resorted to, and so equivocally was it expressed that it excited in the minds of some people grave suspicions, and yet we knew all the parties well, and could answer for their good faith. Bad, therefore, as some have been proved, let us not hastily accept the dictum that all are alike.

Peculiar People.

THERE is certainly no extent of liberty wider than that which is accorded to private folly and fanaticism in the British Empire, and the class of persons who avail themselves of their right to make fools of themselves, is no inconsiderable section of the population. But even in Great Britain the riding of hobbys is limited, and persons are not permitted to carry their own folly to the extent of injuring others, or annoying the public. A wholesome lesson to this effect, was inculcated last week, in the very just and proper prosecution for manslaughter of parents who, with the most guilty disregard of common sense or humanity, allowed their child to die of an unchecked lung inflammation, because they belonged to a fraternity of fanatics, who profess no belief in any curative power, but the direct interposition of the Almighty. The only steps which they took towards saving their child's life, was to secure the prayers of "the Elders," and, as a natural consequence of this neglect, the child died. The penalty of all this folly did not fall upon the parents, simply because the jury could not satisfy themselves that the disease was so trifling, that if proper medical advice had been taken, the child would have lived. The death could not be attributed, beyond doubt, to their neglect, and, therefore, the prisoners were acquitted, but it was distinctly stated that the plea of their disbelief in human aid, would not have, in the slightest degree, protected them from the just punishment of neglecting the proper means to save life. The "Peculiar People" are, no doubt, extraordinary specimens of self-opinionated fanatics, but every word of the law on this point, applies in a minor degree to the neglect of human means under the homœopathic system, and it seems to us that there is a very narrow distinction between the fanatic, who expects in every case of illness the miraculous interposition of God, and the fanatic who, in a similar exigency, confides in atomic divisions of nothing at all.

Bandaging.

AT the examination at the Royal College of Surgeons of London last week, a practical test in this subject constituted one important item of the requirements, and already the anticipation of this test has had the best effect in inducing students to avail themselves of every opportunity of acquiring proficiency in the manipulation. We learn, however, that out of eighty-seven candidates, seventeen were sent back to their studies for six months.

The Comparative Anatomy Lectures at the Royal College of Surgeons of London.

THE following is the programme of the course of twenty-four lectures on Comparative Anatomy to be delivered by Professor Huxley, F.R.S., in the theatre of the Royal College of Surgeons, which commenced on Monday, viz.—General remarks on the *Invertebrata*. The classification of the *Invertebrata*. An account of the organisation of the several groups of invertebrate animals in the following order :—The *Protozoa*, the *Infusoria*, the *Annuloida*, the *Annelida*, the *Arthropoda* or *Articulata*, the *Cœlenterata*, the *Molluscoida*, the *Mollusca*.

Horse-eating.

A GRAND banquet in furtherance of hippophagy is to be held on to-morrow (6th) at the Langham Hotel, and if it be possible to make horse-flesh attractive, no doubt the cookery and the wines of that celebrated hotel will effect the object. We have, however, no confidence in a half-adhesion to hippophagy, as at the last dinner, where as many dishes of French *entrées* were served as of horse-flesh. If that meat can be made sufficiently palatable, the hippophagists ought to be content with it; if not, they cannot ask the public to be so.

University of Cambridge.—Scholarships and Exhibitions for Natural Science in Trinity and St. John's Colleges.

AN examination in Natural Science will be held in Trinity College during next Easter week, and one foundation scholarship at least (of the value of about £80 per annum, tenable for five or six years) will be obtainable by adequate proficiency in that subject. The foundation scholarships of this college are open to all undergraduates of the college in the first, second, and third year of their residence, and to those of other colleges at Cambridge or Oxford in the first year of their residence. The names of candidates who wish to be examined in natural science must be sent in to the master not later than Wednesday, March 18th, together with the subject in which each candidate is prepared to be examined.

At St. John's College an examination will commence on Tuesday, 21st of April, 1868, at nine A.M., and besides two scholarships of £70 per annum, and two of £50 per annum for classics and mathematics, there will be offered for competition an exhibition of the value of £50 per annum, tenable for three years for proficiency in *Natural Science*—chemistry, including practical work in the laboratory, electricity, heat, and light. The candidates will also have the opportunity of being examined in one or more of the following subjects :—Geology, anatomy, physiology, botany ; and they may, if they think fit, offer themselves for examination in any of the classical and mathematical subjects, but excellence in some single department will be specially regarded.

These scholarships or exhibitions are open to all persons, whether they be students in the University or not, who have not yet commenced residence in the University, or who are in the first term of their residence.

Further information is obtainable from the tutors of the respective colleges.

Wells, Drains, and Disease.

IT happens, now and then, that such matters as the outbreak and ravages of a virulent and pestilential fever in a

quiet country village, like Terling in Essex, succeed in arousing the calm indifference of people's minds in reference to matters sanitary, and oblige them to see that it will not do to drink the drainage of dung-heaps and cesspools, and that their houses are better ventilated by means of open windows than by chimneys and drains.

It is a well-known fact that, in country villages, the usual plan of draining the houses is to carry the drains into a covered cesspool, sometimes quite close to the house, sometimes at a distance, but almost invariably this great receptacle of filth is placed in close proximity to the well from which the water-supply for drinking, and other purposes is obtained. The reason, we believe, for this most foolish and dangerous arrangement is to save expense in the laying down of pipes and drains.

In some parts of the country where there is a stiff clay soil it is necessary to empty the aforesaid cesspool from time to time, and so far as our experience goes, and we have paid some attention to the subject, these districts are rarely ravaged by fever. In other parts where the soil is dry and porous, we have seen these same cesspools or "dry wells," as they are sometimes called, and been told that they never require emptying, for the soil sucks up all the matter as fast as it collects in the well. We perfectly remember on hearing this how promptly the question jumped out, "Where is your well for drinking water? In answer, the well is pointed out close by. It is very obvious, therefore, that the matter absorbed from the cesspool will, of a certainty, soak into the well, and pollute the drinking water. Unhappily, it is of no use to tell people this, the arrangement has always been as it is, and so it seems it must remain.

Country surgeons can bear plenty of testimony to fever set up and propagated by drinking poisoned water. We have only to look at the instance of the fever at Terling, and only two or three years ago the whole household of a man named Groombridge, living in Essex, died poisoned from drinking water befouled with the oozings of a dung heap on which had been piled the horrid excreta of beasts that had died of the rinderpest.

We knew well a small town in one of the Midland Counties, standing high, dry, and airy, and yet, at times, ravaged by fever in a dreadful way. When conversing, a short time since, with one of the surgeons of this town, he told us how very perceptibly he had checked the progress of the last outbreak of fever, by making the people bury the excreta of the patients in places remote alike from drains and wells. It had been proved that in very many cases that the drains ran quite close to the wells for drinking water, and any oozing from the old brick drains soon found its way through the porous soil into the well.

Such are the dangers to health from the old cesspool system of drainage; the modern main-drainage plan by means of sewers, is not without its own dangers also, but they are dangers that can, by proper care, be in great measure averted.

A big sewer being but an elongated cesspool, should of course be kept at a distance from any channel of water supply, but this alone is not enough, for here the danger is mainly an *air* rather than a *water* danger.

Strong currents of air set up large sewers often with much force, and thus the sewer gases are forced into the houses, and fever is a certain result.

Thus was caused an outbreak of fever in a well-known watering-place, several years ago, and a much respected surgeon fell as one of its victims. To their praise be it said, the authorities of this place set manfully to work, and soon found that the cause of the epidemic was the forcing of sewer gas into houses where the drains were imperfectly trapped; by inserting ventilators into the sewers, and attending to the security of the traps in the house-drains, they soon succeeded in banishing fever from the place, so that it is now one of the healthiest and most popular of the winter resorts on the south coast.

General Education of Irish Students.

At the preliminary examination in general education, held last week in the Royal College of Surgeons in Ireland, 43 candidates presented themselves. To each student a printed paper in arithmetic and algebra, and an exercise in English orthography, etymology, and punctuation, were given, and each was further subjected to a *viva voce* examination in Latin and Greek. Of the 43 candidates, we believe three obtained first-class certificates, ten second-class, twenty-two were passed as unclassed, and eight were rejected.

Village Ambulance.

We have just visited the coach-building premises of Mr. O'Neill, North Strand, Dublin, where we were shown a very useful ambulance made by him, of which we hope to give a more detailed notice in our next. It will be on view for some days, and we strongly recommend professional men in Dublin to call and examine it. It is made to order of Dr. Bolland, of Gardiner's-place, Dublin, father of the gentleman mentioned in the following inscription, which we copied from a brass plate on the vehicle itself:—"Presented to No. 1 District Daventry Union, in memory of Dr. John Bolland, their Medical Officer, who died April 25th, 1864." The weight of this most elegantly-constructed and useful ambulance is only two cwt.; and it may be drawn by one hand with ease on a road, or in the wards of an hospital.

The triumph of the principle we have advocated respecting the vacant coronership is now secure, the legal candidate having retired. Also, we may announce that Mr. Brown will not go to the poll, as we anticipated from the first. What a pity that Drs. Hardwicke and Diplock cannot settle their relative claims without the expense of a contest which can only illustrate the folly of the present mode of appointment. We hope even yet that something may be done to stay this waste of money.

We learn that an important alteration in the hospital staffs of the Meath and Richmond Hospitals will shortly take place. The surgeoncy to the Richmond Hospital, held for fourteen years by Mr. Fleming, has become vacant by the resignation of that gentleman, who, as consulting surgeon, will still retain his connection with Dr. Steevens' Hospital. His office at the Richmond Hospital will be filled by the appointment of Mr. William Stokes, who resigns his surgeoncy of the Meath Hospital for that purpose. Mr. Stokes, as our readers are aware, is lecturer on Surgery in the Carmichael School, which is immediately attached to the Richmond Hospital. For the vacancy on the staff of the Meath Hospital, justly esteemed one of the first surgical positions in Ireland, there are, as might be anticipated, many claimants. It would be insidious, however, under the present circumstances, to signalise any individual.

Dr. Barker has resigned St. Thomas's Hospital. Dr. Chowne has done the same at Charing-cross, and Dr. Willis at the Westminster. Here then are three fresh vacancies. Gentlemen ambitious of assistant-physiciancies have now an opportunity. We believe there are also other vacancies either in process of filling up, or being created, and by the times these lines are in the readers' hands, there may be more still.

Society Proceedings.

SURGICAL SOCIETY OF IRELAND.

Dr. Adams, President of the College, in the Chair.

This Society met on Friday evening, 17th January, at the Royal College of Surgeons.

Mr. H. G. Croly read the following paper:—

GLOSSITIS.

At a meeting of the Surgical Society held on the 18th of January, 1867, I read a paper on acute idiopathic glossitis, illustrated by seven cases, and at a meeting of the Society, held on the 15th of February following, I detailed the history of another case of unusual severity treated in the City of Dublin Hospital. I now have an opportunity of reading a short history of two cases since met with in my own practice, and also of three cases which occurred in the practice of my friend, Dr. Hadden, of Clonakilty.

On the first of May, 1867, I was requested to visit Mr. D., in consultation with Dr. M'Cormack.

The patient, who is over 70 years of age, and always enjoyed good health, complained on Easter Monday of a soreness about his tongue —three days subsequently, Dr. M'Cormick visited him, and found him suffering from all the ordinary symptoms of acute glossitis of the *left half* of his tongue. Saliva dribbled from his mouth, his speech was thick, he had dyspnœa and dysphagia. The left submaxillary gland was tender to the touch. Leeches were applied to the left submaxillary region, and a purgative administered. At my visit, I found the patient partly sitting up in bed and unable to articulate. I made pressure on the tonsils, and found them free from enlargement or tenderness. The *left half* of the tongue protruded between the teeth, and almost completely filled the cavity of the mouth on the affected side, whilst the right half was natural. I ascertained that the inflammation had gone on gradually for nine days. the patient slept none for some nights. I suggested a free incision should be made at once into the inflamed organ, which the patient consented to, and having him placed in an arm-chair, I introduced a sharp-pointed curved bistoury flat into the mouth and well back to the base of the tongue, and having turned its edge towards the dorsum of the tongue, made a *deep* and *long incision parallel* with the raphe and mid-way between it and the edge of the tongue; blood and serum escaped freely, and I found it necessary, in consequence of the patient's age and debilitated state from want of sleep and food, to plug the incision with lint; pressure was made with the finger on the lint, and thus the hæmorrhage was controlled. The patient was put into bed, and drank some port-wine negus. He expressed himself as relieved at once by the incision. He was ordered beef-tea, and eggs beaten up with brandy.

May 2nd.—Patient says he slept well. The tongue has diminished in size, and shows the deep indentations of the teeth at the left side. As the submaxillary gland remained tender, I suspected that an abscess had formed in it, and having made slight pressure on it, some healthy pus escaped through the incision in the tongue.

A chlorate of potash gargle was prescribed, and also a bark mixture with chlorate of potash.

The patient made an excellent recovery, and the wound in the tongue healed with the usual rapidity, but the speech remained thick for some days, and the *hardness* consequent on the infiltration of lymph into the muscular substance of the tongue gradually diminished.

I got a photograph taken of the patient before the tongue regained its natural size, and I now exhibit it to the members of the society.

Case 2.—Patrick Toole, aged 33 years, a labourer, was in good health until Monday, July the 8th, 1867, when he felt a soreness about the root of his tongue; he continued at work until the 11th inst., he then felt a difficulty in swallowing; his tongue swelled at the *right side*, and was painful; saliva dribbled from his mouth; he had not been taking any medicine; I was requested to visit him on the 12th of July, and found him suffering from the following symptoms:—

Voice peculiar and *speech thick; right half* of the tongue inflamed, and elevated, and *rounded* at the tip, sublingual glands infiltrated and raised on a level with the top of the incisor teeth; anterior surface of the tongue covered with an adhesive white exudation; slight dyspnœa, and some dysphagia; pulse 90 and full.

Treatment.—Numerous punctures were made with a bistoury into the infiltrated sublingual space, which bled freely, and discharged a large quantity of serum. The tongue was well dried, and four leeches were applied on the dorsum at the right side; they bled very freely, and the bleeding was encouraged by washing the mouth with warm water; two purgative pills were prescribed, and his antimonial mixture. The inflammation gradually subsided, but the *hardness*, consequent on the effusion of lymph, remained for several days.

IDIOPATHIC GLOSSITIS.

Case 1.—John M'C., age 25, a small farmer, got a severe wetting four days before; there were smart feverish symptoms ushered in by a rigor, and within forty-eight hours the tongue was swollen and painful; deglutition difficult, and his speech thick. When I first saw him (on the fourth day) the inflammation was chiefly confined to the root of the tongue, and extended to within about an inch of the tip; from my experience of a traumatic case some weeks before, I delayed the incisions usually made in such cases, and gave a mixture containing sulphate of magnesia and tartar emetic, every third hour. On the second day after, I called, and found my patient so much better that he got up, and gone to some old woman, who lived nearly a mile off, to have the cure completed. Within a week he called at my own house, when only a small spot of hardness remained, which was quite painless, and gave him little or no annoyance.

Case 2.—A dairyman, age 45, who had been also exposed to severe cold, and was obliged to remain in his wet clothes all night. I saw him on the third day, having been hurried off by a message to say that he was choking. When I reached him his symptoms were little short of suffocation; the tongue was immensely swollen, and protruded between the teeth; there was profuse salivation; the countenance livid and tumid; his pulse 120, hard and bounding. In this case there was no time for delay, so I immediately made two long incisions into each side of the swollen organ, from base to tip; they gaped widely, and gave exit to a smart hæmorrhage, but in less than half-an-hour my patient was able to lie back comfortably. I gave him, also, the sulphate of magnesia and tartar emetic mixture, and in a few days he was quite convalescent.

Case 3.—A child, 6 years old, the daughter of a coast-guard. Some six or seven weeks previously, she had a mild attack of gastric or remittent fever, from which she had recovered nicely, when she was exposed to cold on a stormy day—the station being in a very exposed position. For the first week I did not see her, but was told by her father that she could swallow very badly; that they noticed her speaking indistinctly, and saliva running from her mouth. On the eighth day I saw her, when, finding pretty distinct evidence of fluctuation, I made an incision in the tongue, at the left side of the raphe, when a large quantity of healthy pus exuded. I ordered a permanganate of potash gargle, and from that hour, my little patient made a rapid recovery.

Dr. Henry Kennedy said that on the first occasion Dr. Croly brought this subject before the Society, he took an opportunity of saying that he had seen a number of these cases of inflammation of the tongue which he looked at from a different point of view from that which Dr. Croly had done. Mr. Croly looked upon them as idiopathic; whereas, he (Dr. K.) considered the swelling of the tongue as secondary to inflammation of the glands and areolar tissue in the neighbourhood. Such cases were comparatively common in erysipleas, scarlatina, and diffuse phlegmon. But they also occurred where no specific disease existed, and of this he had a marked example, in November last, in the person of a young man of 18, admitted into Cork-street Hospital, as it was thought for fever. The patient had fever, but he had also inflammation of the parts under the chin, and the tongue was very much enlarged; it was much swollen and very painful. There was great salivation, a total inability to swallow, and his speech could not be

understood. It was not possible to see into the throat. Leeches applied three times under the chin gave prompt relief and the patient got rapidly well. Nor did the occurrence of inflammation, confined exclusively to one side of the tongue, militate against the views he put forward; for, of course, the inflammation might be confined to one side of the jaw, and then that side of the tongue would necessarily be the side involved. Both the cases given by Dr. Croly himself this evening seemed to Dr. Kennedy to bear out these views; for in one the submaxillary region was admittedly engaged, whilst in the other the parts in the sublingual region were involved.

Mr. WHARTON said that Dr. Kennedy was speaking of an affection of the tongue wholly different from that brought forward by Dr. Croly. He (Dr. K.) considered it to be secondary to an inflammation in a situation near the tongue, whereas, Dr. Croly was alluding to cases in which the affection was not of a secondary but of a primary nature. He thought that the profession in Dublin should be greatly indebted to Professor Geoghegan for his able paper on glossitis, and also to Dr. Croly for placing the results of his cases before the Society.

The PRESIDENT observed that Dr. Croly spoke of surgical glossitis, while Dr. Kennedy referred to medical glossitis. This subject had been treated of by Graves and others, and Boyer alluded to what every one had observed who had seen cases of inflammation of the tongue, that one-half of the tongue was sometimes only affected. The disease was one which required very active treatment, such as free deep incision on the dorsum, the mouth being kept open by a proper instrument, and thus treated was not dangerous: but if neglected œdema of the glottis would, most probably, ensue, as in erysipelas, and cause the death of the patient.

Dr. TUFNELL said it was most desirable that free incisions should be made in the tongue, otherwise, if the patient lived, an abscess would, most probably, form, and one of a most fœtid character. He had seen patients brought into the hospital with abscesses in the tongue almost as fœtid as those which were found in the neighbourhood of the rectum; and it was important that this should be prevented.

Dr. STAPLETON asked did any gentleman ever see any of these cases without their being first a swelling under the jaw or at its angle? Did they ever see the tongue primarily swollen? What he called surgical glossitis was where there was an abscess formed at the root of the tongue. He never yet saw a case of glossitis in which the glands under the jaw were not first affected. No doubt a free incision was necessary when there was much inflammation. It was quite a different thing when there was erysipelas, not only externally but also in the mouth. Then, indeed, there was danger of œdema of the glottis.

Dr. WHITE hoped they would not depart from the subject without some strong expression of opinion as to the best mode of treatment. He had seen but two cases of what he considered true surgical glossitis, one of which was under the care of a friend, the other under his own care. In the former case, deep and long incisions were made. The man had severe rigors, followed by rapid swelling of the tongue. He did not remember whether there was any swelling of the neck. What attracted his attention when he saw the patient was, that the tongue, which was protruded from the mouth, was of a deep purple colour, and one side of it tremendously swollen, while the other was not. The treatment adopted was that recommended by the President—free incision. His friend made incisions, and the man had a good recovery. Some three or four weeks afterwards, he (Dr. White) met with a similar case at Templeogue. The patient was a man employed at a mill in the neighbourhood. He was a hard drinking man, and after one of his bouts he slept out in the field, and got a severe wetting. He was attacked with rigors, followed by swelling of the tongue. He saw him two hours afterwards; the tongue then protruded from the mouth, and he could not return it; both deglutition and speaking were almost an impossibility. He applied eleven or twelve leeches to the man's tongue, causing free bleeding, and in a few hours he was perfectly relieved. He recovered in much less time than the patient whose tongue was scarified. He saw no difference between the two cases in point of urgency.

Professor HARGRAVE said, that some years ago he saw an interesting case of pure glossitis, under the care of Dr. Benson, in the City of Dublin Hospital. There was inflammation at the right side of the organ; the man could barely breathe; the tongue protruded from the mouth, and there was sublingual swelling. A free incision was made, and free bleeding followed. The recovery was rapid. He was certain it was a case of true uncomplicated glossitis. He greatly preferred a good free incision to the use of leeches, in order to guard better against the formation of abscesses; for if they did form at the root of the tongue, they would be found very difficult to manage.

Dr. FLEMING observed that since the discussion on this subject last session he had carefully watched at the Richmond Hospital to meet with a case of true surgical glossitis, but he had not met with one case during the last twelve months. He believed the Surgeons connected with Steevens' Hospital who were present could say the same. It was therefore a disease of comparatively rare occurrence; but no doubt when it occurred it required active treatment.

Dr. CROLY, in reply, said he thought the distinction which had been drawn by the President between surgical and medical glossitis was a very important one. He had met with cases of both, but it was the former only to which he now referred. The effusion of lymph, the result of inflammatory action, was a different thing from the rapid engorgement of the tongue which occurred in cases such as Dr. Kennedy referred to; and the hardness remaining was a symptom of the true glossitis. With regard to Dr. White's observations, he had only to say that there were two classes of symptoms in every disease—the very urgent symptoms and the early symptoms. In the early symptoms of glossitis he had himself used leeches and cut short the inflammatory symptoms. In one case which occurred last year the symptoms were so urgent that Dr. Gray asked him, if it occurred to him, that it might be necessary to open the woman's windpipe if inflammation attacked the base of the tongue. It was very little matter whether the disease was called glossitis or inflammation of the tongue. What he wished to insist upon was the necessity of active treatment.

The PRESIDENT observed that Dr. White spoke of scarification and leeching of the tongue, in contradistinction to what he recommended—a long free incision; but of course Mr. White cannot contemplate, when he speaks of scarification and leeching merely, those severe cases which threaten life by suffocation.

[The remaining papers read at this Meeting will appear in our next.—Ed. M. P. & C.]

LONDON METROPOLITAN POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

THE quarterly report of the Council, after congratulating the members upon the success of their labours with respect to the removal of pauper lunatics to the asylums, the Poor-law Board having, upon their appeal, supported by the influential aid of the Commissioners in Lunacy, issued a circular to the guardians in consonance with the recommendations of the association, and correspondence between the council and the Poor-law Board upon the subject of medical officers' salaries and tenure of office, proceeded as follows:—

"The Board could not well promise more than they have done; but, meanwhile, it is to be hoped that they will, in the exercise of the powers conferred upon them, give a liberal interpretation to the compensation clauses of the Metropolitan Poor Act, 1867, if it should become necessary, in carrying out the new arrangements, to displace any of the Medical Officers, who, having enjoyed for many years what they and every one else deemed to be life appointments, are now told that their appointments are annual, inasmuch as the Poor-law Board have not issued their order of 25th May, 1857, to the parishes.

"Your Council regret to learn that considerable misunderstanding appears to exist as to the proper interpretation of clause 3 of section 69 of the Metropolitan Poor Act, which enacts that after the 29th day of September, 1867, expenses incurred 'for all medicines and medical and surgical appliances supplied to the poor in receipt of relief by guardians under this Act or any of the Poor-law Acts' shall be repaid out of the Common Poor Fund. In some unions and parishes the guardians have compensated their Medical Officers for the stock of medicines on hand, and provided all medicines, &c., since Michaelmas-day last; and this without, in any case, it is believed, diminishing the salaries of the Medical Officers—liberality which it would be ungracious not to acknowledge as it deserves. Other boards, contending that the Act does not compel, and that it is optional with them to provide the medicines, have held their medical officers to the strict letter of their contracts, which require them to provide the medicines.

"Your Council believe that Mr. Hardy and the legislature in-

tended the clause in question to be interpreted literally; and that all medicines and appliances both for the in-door and the out-door poor of the metropolis should be supplied by the guardians at the cost of the Common Poor Fund. It may be hoped that ere long the Poor-law Board will see fit to express their views upon this important question.[1]

"Valuable as the boon of medicines would be, its value would be very greatly enhanced if properly qualified dispensers were appointed to the larger workhouses.

"The metropolitan inspectors, in their joint report (18th January, 1867),—a report which has a deep significance in connection with the passing of Mr. Hardy's Act—recommend that 'whenever the number of sick exceed 100, a dispenser of medicines should be appointed to the hospital.' Why not then to the present infirmaries under the same circumstances? The duty of the Medical Officer should be medical work, and not, as too much of it now is, dispensing and desk work. And this leads your Council to remark upon the large amount of writing imposed upon Medical Officers by the 'Workhouse Medical Relief Book'—a duty which is rendered doubly arduous from the want of proper dietary tables, leading to the crowding of the weekly return with the names of the merely infirm, who, because the 'house diet' is almost universally unsuitable for this class of inmates, have to be treated as 'sick.' Your Council hope that the system will ere long undergo revision. The metropolitan inspectors, in the report already adverted to, say that the Medical Officer should 'regularly visit every patient under his charge, and make a note of such visit on the prescription-card hanging at the head of the patient.' If this were done in every case (as it has long been done in some workhouse hospitals); and if the diet were entered upon another card; and if all visits, prescriptions, and diets were registered, as they might be by a clerk or dispenser; or if the cards were carefully preserved, the objects served by the present system would be attained, and the Medical Officer, freed from the drudgery of the pen, would be able to devote all his time and energies to the higher duties of his place. But it would be necessary to have 'Special Dietaries,' which the inspectors recommend 'should be framed by the Poor-law Board and uniformly adopted in all the metropolitan workhouses.'

"Your Council believe that the inspectors could do no greater service to the sick poor and their medical attendants than by using their great influence to procure the adoption by the Poor-law Board of the foregoing recommendations made by themselves, and which are in complete accordance with the views advocated from the beginning by the Association.

"Up to the present time it would appear that no 'dispensaries' have been opened in the metropolis under Mr. Hardy's Act; but in several of the unions and parishes preliminary arrangements with this object are understood to be under the consideration of the guardians and the Poor-law Board.

"In concluding their Report your Council feel that it would not be right to pass over, in silence, a subject which must be present, and a source of regret to every mind—viz., the suspension of the President by the board of guardians whom he has served so long and faithfully. As the charges brought against Dr. Rogers by a section of the guardians are still *sub judice* it would be unbecoming to express any opinion upon them beyond this, that they appear to be wholly of a personal character, and in no way reflect upon his skill and attention as a Medical Officer.

"Your Council having undiminished confidence in the President rejoice to observe the manifestations of support and sympathy extended to him by the most influential of the guardians, by the press, and by his fellow-parishioners in public meeting assembled; and, relying implicitly upon the justice and impartiality of the Poor-law Board, they look forward to his speedy restoration, without stain or reproach to his former sphere of usefulness."

The PRESIDENT moved the adoption of the report.

The HON. SECRETARY read a correspondence which had been forwarded to the Council by Mr. B. Clarke, the medical officer of the East London Union Workhouse, between that gentleman, the guardians, and the Poor-law Board, on the subject of the supply of medicines for the sick poor in the metropolis, and which raised a very important point—viz., whether section 69 (clause 3) of the Metropolitan Poor Act, 1867, relieved medical officers who had contracted with guardians to find the medicines, from the necessity of continuing to do so, it being supposed that such was the object of the clause.

After an animated discussion, the following resolution

"The meeting having taken into consideration the correspondence submitted between the Poor-law Board and the guardians and medical officer of the East London Union Workhouse, relating to the supply of medicines for the sick poor, in which the board state their opinion that clause 3 of section 69 of the Metropolitan Poor Act, 1867, 'does not interfere with the existing contracts; and that so long as such contracts continue, their terms must be complied with. Hence, where a medical officer has contracted with the guardians to find drugs and medicines, he must continue to do so until his contract has been determined:'

"Resolved, that the Association desires to express the disappointment with which it has learnt the opinion of the Board, and, believing it to have been the intention of the legislature that all medicines, &c., supplied to the sick poor in receipt of relief by guardians in the metropolis, on and after the 29th day of September, 1867, should be paid for out of the Common Poor Fund, requests the Council to memorialize the Board that they would be pleased to exercise the powers vested in them by the Act, and to vary the existing contracts so as to give effect to the intentions of the legislature."

Which, with the foot-note in the Council's Report, explains the drift of the subject, was unanimously adopted, as was also the following resolution:—

"The Association, believing that the time occupied by Medical Officers in dispensing medicines and in keeping the 'Workhouse Medical Relief Book,' is so much time lost to the service of the sick poor:—

"Resolved, that in the opinion of this meeting the appointment of dispensers to the workhouse infirmaries would be true economy; and that by the use of diet and prescription cards (on which all necessary particulars of each case should be entered by the Medical Officer—to be copied thence into the Workhouse Medical Relief Book by a clerk or a dispenser) the ends served by the present irksome and laborious system would be attained, and the Medical Officer be thus enabled to devote the whole of his time to his medical duties."

The proceedings were brought to a conclusion by a vote of thanks to the Officers and Council for their services during the past quarter, and to the President for his conduct in the chair.

---

1 Since the Report was in type, the Council have been favoured by Mr. B. Clarke, the Medical Officer of the East London Union Workhouse, with a copy of an important correspondence between the Poor-law Board, the guardians, and himself, upon this subject; and as the "views" of the Poor-law Board are very clearly stated therein, the Council gladly avail themselves of Mr. Clarke's permission to use the correspondence "as they may think fit." It appears that on the 4th November last, Mr. Clarke wrote to the guardians calling their attention to section 69, clause 3, of the Metropolitan Poor Act, 1867, with the view of getting the medicines, &c., supplied by them at the cost of the Common Poor Fund, in accordance with the terms of the Act. On the 7th November, the guardians wrote to the Poor-law Board, and, after citing the clause, and stating that the Medical Officer "is under a contract to supply the sick poor with medicines," inquired "whether the clause in question has the effect of altering the arrangement between the guardians and Mr Clarke," and what, in the opinion of the Board, "is the proper course for the guardians to adopt?" The Poor-law Board (Nov. 25th) forwarded the letter of the guardians to Mr. Clarke for any observations he might wish to offer thereon; and that gentleman, having (Nov. 29th) stated his belief that the Act required the guardians to provide the medicines at the cost of the Common Poor Fund,—"fortified in this opinion by the action already taken by the guardians of other Metropolitan Unions."—the Poor-law Board replied, on the 16th December, to the inquiry of the guardians as follows:—"That in the opinion of the board, section 69 of the Metropolitan Poor Act, 1867, does not interfere with the existing contracts, and that so long as such contracts continue, their terms must be complied with. Hence, where a Medical Officer has contracted with the guardians to find drugs and medicines, he must continue to do so until his contract has been determined."

The Council submit the foregoing extracts, the upshot of which they think will surprise the members and the public as much as it has surprised them, without a word of comment.

RATE OF MORTALITY IN NEW YORK.—In the city of New York in the year 1867, 23,170 persons died, in a population now estimated at 900,000, or 25·75 per thousand. In Brooklyn the mortality was 8325, in a population of 370,000, or 22·50 per thousand. It is stated that more than 3600 of the persons dying in New York were buried from the hospitals and public institutions, and that among the 19,500 persons who died in the dwellings of the city there were nearly 12,000 children under five years of age, 7000 (in round numbers) being infants not a year old. More than a fourth of the deaths were caused by preventible diseases. The deaths in New York were 3645 fewer than in 1866.

Address.

LESIONS OF CUTANEOUS SENSIBILITY IN DISEASE.

THE INAUGURAL ADDRESS DELIVERED IN THE DINING HALL OF TRINITY COLLEGE.

JANUARY 21, 1868.

By E. W. COLLINS, B.A. Med. Sch.

AUDITOR OF THE DUBLIN UNIVERSITY MEDICO-CHIRURGICAL SOCIETY.

(Continued from page 102.)

ANÆSTHESIA alone, that is without paralysis of voluntary movement, is not a symptom of disease of the spinal cord, save in very exceptional cases, such as softening commencing in the very place where the decussation of the sensitive conductors occurs; a slow increase of fluid in the central canal, as in spinal bifida; or in vertical division of the cord (diplomyelia). This must become evident when it is stated that paralysis of voluntary movements, in diseases of the cord, is an essential symptom not only of an alteration of the anterior columns everywhere except near the medulla oblongata, but also of an alteration of the whole central part of the gray matter. Anæsthesia regarded then as constituting one—and one only—of a group of symptoms in disease of the spinal cord, must be, and in reality is found to be, indicative of an alteration of the gray matter; and this conclusion seems to hold good with respect to the loss of each of the various kinds of sensibility. For, alterations limited to either of the white columns do not cause anæsthesia of any kind. The result of such alterations is either paralysis or hyperæsthesia.

It is a remarkable fact that a transverse section of the posterior columns, in former times the only pretended channels of the sensitive impressions, instead of, as might hence be predicated, being followed by a diminution of sensibility, is followed by the very reverse. The result of this operation, whether performed in the lumbar, dorsal, or cervical regions, is always the same. There is a manifest hyperæsthesia in the various parts of the body which receive their nerves from the portions of the cord behind the section. A section of either the anterior or lateral columns is also followed by a slight degree of hyperæsthesia. It is also one of the results of a transverse section of certain parts on the posterior side of the encephalon, namely, the restiform bodies, the cerebellum with its superior peduncles (processus e cerebello ad testes) and the tubercula quadrigemina.

Hyperæsthesia, therefore, is chiefly characteristic of lesions of the posterior columns of the cord, and of the portions of the brain which are their direct continuation upwards. Most frequently, like anæsthesia, it coexists with loss of movement: unlike it, however, it may exist alone.[1] This occurs in cases of alteration, very little extended, of the posterior columns, or of the cerebellum. But there is much less hyperæsthesia when the posterior columns are altered in a great portion of their length, even though the posterior roots and the gray matter remain normal. This is explained by the fact that many conductors of sensitive impressions which pass for a short distance in these columns are injured: and, although the same causes of hyperæsthesia exist then, as after a simple section, this excess of sensibility does not show itself on account of the diminution of sensibility due to the alteration of the posterior columns. There is a kind of compensation, in such cases, between the causes of anæsthesia and hyperæsthesia, so that the degree of sensibility remains nearly normal.

It is, however, as a symptom of a diseased condition of the membranes which invest the nervous centres that, within the last few years in our own isle, the occurrence of hyperæsthesia has acquired such a significance. Olliver,[2] indeed, in 1837, in his celebrated treatise on the diseases of the spinal marrow, noticed this increase of sensibility in spinal meningitis, and regarded it as a means of diagnosis between inflammation of the membranes and of the substance of the cord: the latter being usually accompanied by diminished sensibility. But, long previously, from the times of Vieusseux,[3] in the commencement of the present century, it had attracted notice in the course of a disease of an epidemic nature, the pathology of which was closely connected with inflammation of the membranes of the brain and spinal marrow. I refer to that remarkable disease, epidemic cerebro-spinal meningitis, which, long known on the continent of Europe and North America, has, within the past few years, a second time visited our shores. In adopting for it this title, I merely follow in the steps of Tourdes, of Mayne, of Niemeyer, of Burdon-Saunderson, of Hirsch, of Mannkopf, and of Stillè, names ever to be associated with its history.

Of this disease, during the epidemic at Strasbourg in 1841, Tourdes[1] regarded hyperæsthesia, whenever present, as absolutely characteristic; and since that time others[2] have so frequently observed it, that they too have dared to hold similar opinions. Though we may not concur fully in these sentiments, we cannot hesitate to admit its importance as a symptom. During the recent epidemic it was a condition far from infrequent. On the contrary, its absence was rather the exception. Sometimes the whole, sometimes portions only, of the surface of the body were sore to the touch, and in extreme instances the slightest movement caused exquisite pain. Niemeyer,[3] who also describes it, states that it is sometimes followed by cutaneous numbness or insensibility, which he ascribes to pressure upon the posterior roots of the nerves by the products of inflammation. Anæsthesia, indeed, in this disease, in point of constancy as a symptom, is the very reverse of hyperæsthesia. It has been observed much less frequently, and has been almost universally[4] regarded as expressive of a general state of depression.

Anæsthesia further may be due to alterations of the sensitive nerves in any part of their course, to diseases of the encephalon, and to the poisonous action of various substances. Rut there is a form of anæsthesia much less known, dependent on a morbid reflex action, which may arise in diseases of all the viscera, and from irritations of any sensitive nerve in any portion of its length.

The possibility of a paraplegia more or less complete, without visible alteration of the spinal cord or of its nerves, and dependent on affections of the urinary organs,[5] now admits of no doubt. Other viscera also of the abdominal and thoracic cavities[6] may be the starting points of a paralysis. In the same manner the production of anæsthesia alone from irritation of the periphery is as common as that of paralysis. Cases are on record which abundantly illustrate this proposition—cases of anæsthesia of the lower limbs due to sciatica;[7] of the arm to a cervicobrachial neuralgia; of the face to neuralgia of the infraorbital nerve;[8] and of anæsthesia more or less extended due to various forms of irritation of the skin.[9]

Hyperæsthesia also not infrequently has been found similarly associated. Trousseau[10] has noticed its occurrence, as almost constant, at the peripheral termination (point d'expansion terminale) of the affected nerves in neuralgia—especially in the neuralgia which accompanies herpes zoster—and as best marked in the intercostal, lumbar, and crural forms of this affection.

At first, indeed, and for some time, there are often only phenomena indicating exaltation of sensibility; but subsequently, with the continuance of the malady, the sensibility of the parts, previously exalted, may become much diminished.

In many of these cases the affection has subsided speedily after the cessation of the irritating cause, and, where an autopsy has been made, there has been no visible alteration of the nervous centres. These facts tend to show that the symptoms were not due to a central nervous affection, but to an irritation of some centripetal nerve.

As another very remarkable instance of the occurrence of both hyperæsthesia and anæsthesia, without accompanying lesions of the brain or spinal cord, may be noticed the celebrated Epidêmie de Paris in 1828. It has been described by Chomel[11] and subsequently by Graves[12] as commencing with sensations of pricking and severe pain in the integuments of the hands and feet, accompanied by so acute a degree of sensibility that the patients could not bear the parts to be touched by the

bed-clothes. But after some time—a few days, or even a few hours—a diminution, or even an abolition of sensation took place in the affected members. They became incapable of distinguishing the shape, texture, or temperature of bodies: and finally they were observed to become altogether paralytic. The injury was not confined to the hands and feet alone, but, advancing with progressive pace, extended over the whole extremities. Persons lay in bed powerless and helpless, and continued in this state for months. At last, at some period of the disease, motion and sensation gradually returned, and a recovery generally took place, though in some instances the paralysis was very capricious, vanishing and again returning. The French pathologists, it is said, searched anxiously in the nervous centres for the cause of this strange disorder, but could find none. There was no evident lesion, functional or organic, discoverable in the brain or spinal marrow. Here, then, is a singular instance, not merely of peripheral paralysis, but of peripheral anæsthesia and hyperæsthesia.

But anæsthesia and hyperæsthesia are not the only, or even the best-known, forms of reflex phenomena which may be due to irritations of sensitive nerve-fibres. Changes in the nutrition of other parts of the body may also thus be produced—alterations of nutrition, which, Brown-Séquard endeavours to prove, are the result of an action of the cerebro-spinal axis reflected upon itself through the nerves going to its blood-vessels.

Morbid changes of nutrition in the nervous centres having as their issue insanity in its various forms, and even the general paralysis connected with it, epilepsy, chorea, catalepsy, extasis, hydrophobia, tetanus, hysteria, and all the varieties of nervous disorders may be the result of a simple and often slightly-felt, or even unfelt, irritation of some sensitive nerve; and the suppression of these irritations may promptly cure the patient, just as in cases of epilepsy. Many other morbid influences also might be mentioned as due to alterations of the centripetal nerves: but we will content ourselves with merely noticing the close relationship which often exists between skin affections[1]—the zona, pemphigus, erythema, urticaria—and neuralgia; inflammations of the various viscera and extensive burns;[2] sudden death by stoppage of the heart's movements and the influence of very cold drinks or blows upon the abdomen; the reflex influence of injuries to the trigeminal nerve upon the eye;[3] and the reflex influence of one eye upon the nutrition of the other.

The influence of reflex irritations upon the secretions is also full of practical interest. Any irritation of the eye or of the mucous membrane of the nose causes an increase in the flow of tears; and it has been shown[4] that when, through injury to the trigeminal nerve, the eye has lost its sensibility, tears are no more shed when this organ is irritated. Other secretions also can be produced by reflex action—the secretion of milk and of the menstrual fluid by irritation of the mammæ; of saliva by irritation of the mucous membrane of the stomach by food; of the gastric and pancreatic juices and of bile by an excitation of the nerves of taste; ptyalism[5] and even perspiration[6] by neuralgia.

Great importance attaches to the knowledge of these facts; and the history of the treatment of disease by means of the powerful influence of an excitation of sensitive nerves of remote organs would afford us, doubtless, as many interesting facts as the history of the reflex production of secretions and morbid changes.

Passing from this to the sympathetic system, curious lesions of sensibility are again presented to us. The experiments of Claude Bernard[7] have fully demonstrated the results of injury to this nerve in the neck. Paralysis of it he has shown to be followed by hyperæsthesia on the corresponding side of the face; irritation of it by anæsthesia – effects which seem principally due to the increased or diminished quantity of blood in the vessels.

In contrasting these lesions of the sympathetic in the neck with those of a lateral half of the spinal cord in the mid-dorsal region, with regard to their effects on the side of the face and on the lower limb of the corresponding side, it is remarkable how close an agreement is found. So close, indeed, is this agreement that, reasoning from these and other facts, the important conclusion has been arrived at by Waller, Brown-Séquard, and still more recently by Claude Bernard, that the sympathetic is essentially the great nerve of blood-vessels; and that, far from being a distinct nervous centre, as was formerly, and even still too frequently is, imagined, it is itself merely a great and peculiar portion of the cerebro-spinal axis, from which its many branches issue at a point corresponding to, or immediately above, the middle of the dorsal region of the spinal cord.

There is something very beautiful in the manner in which loss or diminution of one sense is followed by increase in the intensity of others, or rather, as Abercrombie remarks, by an increased attention to the indication of the other senses. The blind acquire a surprising delicacy of touch, even to the extent in some cases of distinguishing colours; the deaf and dumb the habit of understanding what is said to them by watching the motions of the lips of the speaker. These facts excite our wonder. Yet we must admit that, even curious as they are, they are surpassed by the accredited record[1] of a French gentleman, with whom, though having lost every sense except the feeling of one side of his face, his family acquired a method of holding communication by tracing characters upon the part which retained sensation.

Cutaneous sensibility, in truth, is as distinct an endowment as the sense of vision. Neither inferior nor more common, its nerves, though necessarily widely extended over the surface of the body, are as appropriate as if they were gathered into one trunk, like those belonging to the organs of vision and of hearing. The most necessary of the senses, it is enjoyed by all animals, from the lowest to the highest in the chain of existence.[2] Distinct from the others, it is the most important of any: for it is through it alone that some animals possess the consciousness of existence, and, to those which enjoy many, this is essential to the full powers with which they are endowed.

With these brief and imperfect notices, I must be content to dismiss the subject, not that it is in any way exhausted, or indeed handled in the manner such a theme deserves. Sufficient, however, has, I trust been stated to stimulate to further inquiry, and to induce more careful observations of cutaneous sensibility in disease. Should such happily result. in however small a degree, our meeting this evening shall not have been wholly without profit.

From these deeper studies, turning once more, merely for a moment, to a consideration of the general interests of the society, let me conclude by urging on the members the necessity, on their part, for action. We desire not merely your names to swell its numbers. We ask much rather that your best energies be enlisted in its service. Active members, you can each much further; inactive, much retard the advance of our society. Let our meetings be as few as you will, but let them be full of vigour: for energy begets energy, even, as in nature by an immutable law, motion is induced by motion. Let me invite you by your regular attendance to evince the sincerity of your sympathy; and, unanimous in our efforts, let us all, feeling, as members, our individual responsibility, endeavour to bear our part, to lend our aid, towards the common weal. Thus—and thus only—we shall succeed.

We have launched our vessel in safety upon a calm but treacherous sea. The auspicious day of her departure has arrived. Decked with colours, amid the congratulations of an admiring multitude, she sails forth. Strong hands, stout hearts are needed to guide her through the shoals and quicksands of the channel. May prosperity await her.

"Let us then be up and doing,
With a heart for any fate;
Still achieving, still pursuing,
Learn to labour, and to wait."—Longfellow.

NEW WORDS IN MEDICAL READING!

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I am for ever getting puzzled of late with new words occurring in my medical reading, for which I can find no meaning anywhere; the English Dictionary, Copland's Dictionary, the Surgical Dictionary, any dictionary knows none of them. I am kept back, so that I have not up to this hour got on further than your journal of January 8th inst., and I am now entangled in Dr. Moore's case of "Epigastric Neuralgia with Spanæmia,"

1 Abercrombie on the Intellectual Faculties.
2 Sir Charles Bell on the Hand.

whatever this ungenerous term means. A few pages previously Dr. Kennedy coined three words which, of course, will hereafter be picked up and occur in our light reading, as so much Arabic or Hindostani to many. In your journal of the previous week I was knocked all of a heap by that poxy word, Enthetic, used by somebody. When examined for my M.D. at the University of London, I was very nearly rejected for using the word "Paresis," as signifying partial paralysis; my examiner, Dr. Tweedie, insisting there was no such word, although I pledged my honour I had found it in Dr. Mason Good's "Practice of Physic." Since then I have often met with it in the journals, and perhaps so has Dr. Tweedie, but what notion can he or anybody have of Dr. Moore's "Atelectatic Focus," of the extent of a "Walnut Sclerotic," or, though not so hard, his "Ampullular Dilatations?" Now that medical pedantry has become rampant, will you kindly say if any investment made in medical glossaries, such as Fowler's or Mayne's, would at all help a man so bewildered, and if so, what investment would you recommend?—I am, sir, yours faithfully,

J. Carey, M.D.

Taunton.

SEA-SIDE DRAINAGE.—WORTHING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—To the article that appeared in the Medical Press and Circular of the 4th of December, 1867, on the Drainage, Water Supply, and system of irrigation adopted at Worthing, I am sure I may trust to your spirit of fair play to insert the following reply.

1st. *As to the fact of the sewage wells and the wells from which the supply of water is obtained, being within fifty feet of each other, and therefore an assumed risk of percolation from the former into the latter. This is practically altogether impossible.* The walls of the sewage wells, which are thirty feet deep, are constructed of the best bricks, set in cement, and have a thickness of 18 inches at their base. The stratum in which their bases are set is not chalk but marl, a mixture of chalk and clay, of several feet in thickness. This material is so well-known for its retentive power that it is largely used in the neighbourhood for the formation of the beds of ponds, &c., so that, if by any possibility there were a chance of the escape of sewage through the walls of the sewage wells it would be effectually prevented from passing farther, either in a downward or lateral direction by this stratum of marl; moreover, between this and the source of our water supply, that is in the perpendicular direction, there is a distance in the instance of the old well of 335 feet, and the new well of 365, the former being 365 feet deep, and the latter 395, a distance I apprehend, if there were any escape through the walls of the sewage wells and the marl, sufficient to purify even sewage; practically, therefore, in the perpendicular direction, contamination in the minutest degree of the source of our water supply is impossible. The sewage well is, likewise, every day completely emptied.

With respect to the contamination *laterally* of the water in the wells, this is equally impossible, for the force of gravitation in this direction would be inoperative, and if any escape of the sewage were possible through the sides of the sewage well, it would have to pass through the fifty feet of impervious marl before it reached the water wells, and here there is an insurmountable obstacle in the shape of an air-tight iron cylinder in the instance of the old well of seventy feet in depth, and of the new one of one hundred feet. I repeat, therefore, that the contamination of our water supply by *the* sewage is altogether impossible.

But if any further evidence be required of the admirable quality of the water and its freedom from contamination, it is found in the analysis of Professor Redwood in 1865, which I subjoin.

"*Report on the results of a chemical analysis of the Worthing Well Water, in December*, 1865.

"The water as received was free from colour, perfectly bright and well aerated. One Imperial gallon contained 22·37 grains of solid matter.

"The hardness of the water in its natural condition was 16·3 degrees; but after boiling for thirty minutes the hardness was reduced to two degrees.

"The organic matter present in one gallon was oxidised by 0·0077 gr. of oxygen.

"Comparing these results with those obtained by Mr. E. C. C. Stanford some years back, it will be seen that very little change has taken place in the composition of this water, the total amount of saline matter per gallon differing by less than two grains. The principal alteration is in the amount of Carbonate of Lime, which has increased; but the quantity of the Sulphates and Chlorides of Calcium and Magnesium has diminished. This change is rather advantageous than otherwise, for it is the latter salts which give permanent hardness to the water, the hardening influence of the Carbonate of Lime being readily removed by boiling. Thus the hardness of the water in its natural condition is at present two degrees greater than it was in 1857; but its permanent hardness, that is to say, its hardness after the Carbonate of Lime has been precipitated by boiling, is two degrees less.

"The most valuable character of this water, in a sanitary point of view, is its comparative freedom from organic impurity. In this respect it will bear comparison with the best potable waters known.

"The general quality of this water may be better judged of by comparing it with the waters supplied to the metropolis. Analyses of these waters were made by Dr. Frankland, and published in the Registrar General's returns, during the same month that the sample of Worthing water was drawn for this present analysis, that is to say, December, 1865.

December, 1865. Names of Water Companies.	Solid Matter in 100,000 parts of the Waters.	Organic and other Volatile matter included in col. 1.	Amount of Oxygen required for oxidation of Organic Matter.	Degrees of Hardness. Permanent.	Temporary.	Total.

"T. Redwood, Ph. D.,
"Professor of Chemistry to the
"Pharmaceutical Society of Great Britain."

You then say the well is in rather an indifferent condition. This is so in the instance of the old one. The bore after ten years of service having become somewhat obstructed, and the supply of water therefore diminished, but this in no way interferes with the *quality*, and the short supply is already remedied by the new well now being sunk, and which will be completed in a very few days,[1] the bore of which is four times as large as the old one. From this well, it is the opinion of our consulting engineer, C. E. Rawlinson, Esq., that the supply of water will be ten times as much as from the old one, and equal to every requirement of the town, allowing for its steady increase, for many years to come.

2. *With reference to the scheme of irrigation.*—To the *economical* aspect of this you appropriately observe you have paid less attention than to the *sanatory*. I will therefore merely remark that not only the Italian rye grass but oats, roots, and cabbage can be grown with profit, and that the company is fairly remunerative; last year, I am informed, it paid £10 per cent. but that this year it will probably be less.

With regard to its *sanatory* aspect, it is, I assume, a recognized principle in sanatory science equally with that of medicine, that a poison however potent, whether this be that of typhoid fever, ague, or even cholera, that there is a point of dilution or diffusion at which the poison ceases to produce any effect whatever. This must be so. Guided by this principle, the sewage is conveyed seven-eights of a mile from the works in iron pipes hermetically sealed, and at the time the company was formed, was carried sufficiently far from the town to be free from all risk. Building operations, however, have lately been extended in that direction and the question has recently

1 Since writing the above the new well has been completed, and the supply of water is most copious and admirable in quality.

more than once been raised, whether the time must not soon come when the irrigation of these lands, if done at all, should not be carried on at a greater distance than at present. There are three medical men on the Local Board of Health, all of whom, I believe, thoroughly comprehend this subject, and the Board, you may rest assured, will take care whilst exercising the utmost consideration for the interests of the proprietors, that the health of the town shall be the primary consideration, and your observations will support me in the opinion I have for a long time held that with us—*a Health Resort*—there should have been no irrigation at all.

When it is a question as in an inland town of the polution of a river or the irrigation of the land, of the two evils the latter may well be selected, but in our case, where the arrangement was originally made for discharging the sewage into the sea, no consideration of profit or experiment by individuals ought to have allowed this plan to have been departed from. I may say, however, that the design of the whole of these works have been, from the commencement, under the superintendence of the eminent civil engineer, C. E. Rawlinson, Esq., Chairman of the Royal Commission, for inquiring into the polution of rivers, and the best means for the disposal of the sewage of towns; and, whilst he is convinced that the contamination of the water with the sewage at the works does not now, or ever can take place (and in this I fully concur), he is equally convinced that the irrigation of the land at the present time is in no way a source of danger to the health of the town. I am persuaded, however, that at an early date (as soon as it can be done with justice to the proprietors, who, with laudable zeal, were anxious to try the experiment of what may almost be considered a national question, viz., the application of the sewage of towns to the fertilization of the land), the irrigation of these lands will be discontinued, and the whole of the sewage, as formerly, be discharged into the sea, far away, and to the east of the town.

On the question of the contamination of the surface wells, with the sewage used for irrigation, this is equally impossible with the water at the works. The irrigation is carried on to the east of the town, at a situation directly opposite to the supply of water to these wells, and from the configuration of the country the surplus sewage, if any, would be carried still further away, whilst the supply of water to the surface wells is from the valley of the Arun, a most extensive source, lying upwards of ten miles off, to the west and north-west, for it has been invariably found that after periods of drought, the surface wells never rise till this valley becomes flooded by the overflowing of the banks of the river, and with respect to the supply of water to the deep wells, this is so permanent and copious, when the bore is in good order, that it must be from a far more extended source than even this.

Compared with its population, it may safely be affirmed, that Worthing is in the van of all other towns for the costliness and perfection of its system of drainage and water supply—privies have been abandoned throughout and water closets substituted, even for the use of the poorest houses—but from its novelty, difficulties have necessarily from time to time arisen, but during the ten years that these works have been in operation, no absolute failure has taken place with the exception of one day in 1865, when, during an unprecedentedly heavy storm, the pumps were unable to lift the storm waters and the sewage together, the result was they backed through the sewers into the town, and flooded the basement floors of many of the houses, causing an outbreak of fever. This cannot occur again, for the bulk of the storm waters now pass away directly into the sea through other channels; but even should that portion of these waters, which find their way into the sewers, be greater than the pumps can remove from the sewage well, an outfall sewer has been constructed in connection with it, by which they will be conveyed away instead of being thrown back upon the town.—I am, sir, your obedient servant, WALTER G. BARKER, M.B.Lond.

The Steyne, Worthing, Jan. 17, 1868.

THE Missouri Medical Association was duly resuscitated on the 12th of December, after a long sleep of ten years, and has inaugurated some wise measures relating to the future prosperity of medicine in the State. A communication from the St. Louis Medical Society, asking of the Legislature a Board of Medical Examiners to be appointed by the Missouri Association, with power to grant licenses, was adopted, and a committee appointed to prepare a suitable memorial. They also endorsed most emphatically the stand taken in the matter of medical education by the recent Convention of Medical Teachers.

THE BRITISH LYING-IN HOSPITAL AND THE FEMALE MEDICAL COLLEGE.

A COMMUNICATION to a contemporary from Dr. Henry E. Eastlake, the Physician to the Hospital, discloses a most unsatisfactory result of the connection of that institution with the Female Medical College, and affords a cogent warning to the profession not to place themselves in the position of alliance with the administrators of that establishment. The facts, as narrated by Dr. Eastlake, are in the main not controverted. A patient of the hospital having been seen by Dr. Eastlake, and considered in favourable progress of parturition, was afterwards visited by two pupils of the Female Medical College, midwives in the hospital, and the application of the forceps surreptitiously attempted by them in Dr. Eastlake's absence. An investigation was held by the Board, and the verdict delivered was, strange as it may appear, one of censure on the pupils, *and a request for the resignation of Dr. Eastlake.* In explanation of this inconsistent decision, that gentleman states that a short time previously a number of the party who were favourable to the proposal for amalgamating the Female Medical College and the Hospital, suddenly and simultaneously made themselves annual governors of the hospital by a payment of two guineas each, and by a *coup d'etat* ousted the medical officers from their share in the hospital administration. Dr. Eastlake had firmly expressed himself as against the amalgamation, and the evident deduction is that this occasion was seized to get rid of him. If the ephemeral governors succeed in forcing Dr. Eastlake to resign, which we don't anticipate, they can only do so in disregard of public and professional feeling—a course which cannot fail to bring the British Lying-in Hospital to a level suitable for its incorporation with the Female College.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a general meeting of the Fellows, held on Thursday, January 30, the following gentlemen were admitted members of the College:—George Charles Bright, M.B. Oxon, 8, Southwick-crescent, Hyde Park; John Cavafy, M.B. Lond., 26, Pembridge-gardens, Bayswater; Charles William Cooper, M.B., Cantab., 2, Grenville-street, Brunswick-square; Michael Comport Grabham, M.D. Aberdeen, Madeira; Alexander Silver, M.D. Aberdeen, 8, Gray's-inn-place. At this meeting the following were duly admitted licentiates of the college:—Joseph Groves, Carisbrook, Isle of Wight; Stephen Wootton Bushell, Bickley.

UNIVERSITY OF OXFORD.—The Regius Professor of Medicine (Dr. Acland) proposes to resume a course of Clinical Instruction at the Infirmary every Tuesday and Saturday, at 11 o'clock, beginning on Saturday, February 15. The Professor will be in his rooms at the Museum every Thursday, at 12 o'clock, beginning on Thursday, February 13, for the purpose of aiding members of the University who may need advice or help in any department of medical study. Gentlemen who have passed Moderations and are studying for the Natural Science School, or have passed it, can attend the clinical course.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At the quarterly examination, held on the 29th January, the following gentlemen passed their preliminary examination, viz.:—

John G. Allen, Robert H. B. P. Anderson, James R. H. Anderson, Arthur E. J. Barker, William H. Barr, Thomas Baly, John T. B. Bookey, John T. Burgoyne, Henry Byrne, George G. Cuppage, Charles E. Daly, Charles J. Diamond, John J. C. Doherty, William B. Drew, James W. Gamble, William A. G. Gilligan, Charles R. M. O. Hearn, Daniel J. Hearn, Stephen F. Hill, Lewis A. Irving, John L. Kealy, Daniel J. Kean, Michael Matthews, James M'Nally, Joseph M. O'Brien, Charles O'Connor, Richard C. M. Pooley, John C. Quinn, Nicholas S. Smith, William P. Sullivan, Francis J. Tirney, Edward Williams, and Patrick J. H. Williams.

NOTICES TO CORRESPONDENTS.

Proofs reaching authors in England on or before Friday morning, are expected to be returned to the Editor, at the office, 20, King William-street, Strand, W.C., before five P.M., on Friday afternoon. Proofs reaching authors on Friday evening or Saturday morning *must* be returned to the office by two P.M. on Saturday, which is an early closing day. Duplicate proofs are sent to authors, in order that they may correct and return one copy, and keep the other for private use. Contributions should be LEGIBLY written, on one side of the paper *only*.

All Communications and Letters must be authenticated by the name of the writer, though not necessarily for publication.

VARIETIES OF FOOD—THEIR CHEMICAL COMPOSITION AND NUTRITIVE VALUE.

(Continued from page 108.)

Meat.—There is hardly a class of individuals, however poor they may be, who do not make a strong effort to obtain meat. It would seem, therefore, to be a necessary article of diet. In this metropolis the in-door operatives eat it to the extent of 14·8 ozs. per adult weekly; 70 per cent. of English farm labourers consume it, and to the extent of 16 ozs. per man weekly; 60 per cent. of the Scotch, 30 of the Welsh, and 20 of the Irish. The Scotch, probably, have a larger allowance than the English, considering that braxy-mutton is the perquisite of the Scotch labourer; but the Welsh have only an average amount of 2½ ozs. per adult weekly; and the Irish allowance is still less.

It is difficult to obtain accurate returns of the quantity of meat consumed in London; but if the computation of Dr. Wynter be correct, it is not less than 30¾ ozs. per head weekly, or about 4½ ozs. per day for every man, woman, and child. In Paris, according to M. Armaud Husson, who has carefully collected the *octroi* returns, it is rather more than 49 ozs. per head weekly, or just 7 ozs. a day. We are not, therefore, such large meat eaters as the French.

Butchers meat differs very much in nutritive value according to the proportions of fat and lean; and there is a strong prejudice in favour of beef as the strongest kind of meat. In reality, however, the lean of all meat is of nearly the same nutritive power, provided it is digested; but in this respect there are large differences. The flavour also varies with the nature of the animal, and with its mode of feeding. Pampas-pig, and indeed most wild swine, are horribly rank, but by proper feeding they become delicious. In store animals the proportion of lean is always greater than the fat, and the solid matter does not amount to more than 28 or 29 per cent.; not so, however, in fat animals, for then the fat is largely in excess of the lean, and the solid matters make up about half the total weight. The tendency, indeed, of the fattening process is to substitute fat for water in the carcass; and the quality of the meat depends on the intimate intermixture of fat with the muscular tissue. All animals are not alike in their method of depositing fat, for some put it upon the surface of the body, and others accumulate it among the viscera. The art of breeding and feeding stock is to overcome both of these tendencies, and at the same time to produce a fat which will not melt or boil away in cooking. Oily foods have always a tendency to make soft fat.

The average proportions of fat and lean in the offal and carcasses of animals are shown in Table No. 6 (p. 130), and Table No. 3 (p. 84) exhibits the proportion of the principal nutritive constituents in ordinary joints of meat. Lean meat is evidently deficient of carbonaceous matter, and this is best supplied in bread or potato; but in fat-meat, considering that the nutritive power of fat is twice and a-half as great as that of starch or sugar, the carbonaceous matter is often in excess of the right proportion; it is remarkably so in pork, which will bear dilution with the flesh of rabbit, poultry, and veal.

The amount of bone in meat varies: it is rarely less than 8 per cent. In the neck and brisket of beef it is about 10 per cent., and in shins and legs of beef it amounts to one-third, or even half the total weight. The most economical parts are the round and thick flank, then the brisket and sticking-piece, and lastly the leg. In the case of mutton and pork, the leg is the most profitable, and then the shoulder.

Horse-flesh is hardly known in this country, except as canine food; but on the Continent, and especially in Germany, Belgium, and Switzerland, it is regularly sold in the public markets, and is considered superior to beef. Possibly we have often eaten it on the Continent without knowing it. A *Châteaubriand*, or double beef-steak of Paris, is said to be best of horse-flesh; and no doubt the frequenters of the *restaurants* of Paris have unwittingly acquired a fondness for it, and have relished it as good beef. A story is told by a writer in the *Saturday Review* of a Frenchman who blandly remonstrated with an Englishman for his scorn of French beef. "I have," he said, "been two times in England, but I navère find the bif supérieur to ours. I find it vary conveenient that they bring it you on leetle pieces of stick, for one penny, but I do not find the bif superieur." On hearing which, the Englishman, red with

astonishment, exclaimed, "Good God, sir, you have been eating cat's-meat." To be serious, however, there is no reason why the flesh of healthy horses should not be used as human food. It has many powerful advocates, among whom is the great naturalist, Geoffrey St. Hiliare.

Venison and the dark flesh of other wild animals differs from butcher's meat in the circumstance that it is leaner, and that it contains more blood; but its nutritive power, when properly cooked, is not inferior to that of beef or mutton, and it is always more digestible.

The offal of meat constitutes about one-third of the entire weight of the slaughtered animal. It consists of the blood, the head and its contents, the tongue and brain, the heart and lungs, the abdominal viscera—as the diaphragm, the liver, spleen, pancreas, stomach, intestines, and reproductive organs, and the feet, tail, and skin. In the case of the pig, the skin and head are part of the carcass.

Nearly all these, when properly treated, are good for food. The *blood* of the pig is mixed with groats and fat, and converted into *black-pudding*, which contains about 11 per cent. of nitrogenous matter. The *stomach* of the bullock is cleaned and boiled for *tripe*, which contains 13 per cent. of albumen and 16 of fat. The *heart*, *lungs*, and *pancreas*, which constitute about 7 per cent. of the live weight of animals, are as nutritious as lean meat. The *head*, especially, of the ox, makes good soup; but it requires long boiling to extract the nutriment. Boiled for 8 or 9 hours, it will yield one-fourth of its weight of gelatine, besides which an ox-cheek will furnish about 4 lbs. of good meat. Bones also contain much fat and nitrogenous matter, which they give up when broken small and boiled for many hours. Six pounds of bones are equal to one of meat for nitrogen, and to nearly two lbs. of meat for carbon.

Bacon differs from fresh meat in the relatively large amount of fat and small proportion of water. It is an almost universal article of diet among the labouring classes. 74 per cent. of farm-servants use it to the extent of from ¼ lb. to 2 lbs. per adult weekly. 69 per cent. of the Scotch use it, and 40 per cent. of the Irish. It is preferred to butcher's meat for many reasons—as that it goes further, especially with children, who don't generally like fat; it has more relish; it is easily cooked, and suffers less waste in cooking; besides which, it is easily kept, and is always handy. Preference is nearly always given to the English bacon, notwithstanding that it is double the price of American, for the flavour is better, and it does not boil away in cooking. No doubt the inferiority of American bacon is due to the method of feeding the pigs, for they run wild and eat large quantities of acorns and oily nuts. Good bacon should not lose more than from 10 to 15 per cent. in cooking.

The nutritive value of both green and dried bacon are shown in tables No. 3 and No. 4. Their peculiarity is the large amount of carbonaceous matter they contain as compared with nitrogenous. Calculated as starch, it is as 20 or 24 to 1. Hence it is that it will improve the value of substances rich in nitrogen, as eggs, veal, poultry, beans, and peas.

Poultry and the *white meat* of *rabbits* are not of themselves very nourishing. They contain too much nitrogenous matter and too little fat. In the case of aquatic birds, as the goose and duck, the fat is more abundant; but it contains certain flavouring matters which are not easy of digestion. The darker flesh of game is also somewhat indigestible, and requires management in its culinary treatment.

Fish is not a favourite article of diet with the labouring classes, unless it is salted or smoked, and then it is chiefly used for its flavouring qualities. There is a prejudice that it has no nutritive strength, and it arises, perhaps, from the circumstance that it does not easily satisfy hunger, and is quickly digested, but the inhabitants of our coasts use it largely as food.

The nutritive value of the white varieties of fish, as whiting, cod, haddock, sole, plaice, flounder, and turbot, are shown in the Tables No. 3 and No. 4, and it will be remarked that they contain only about 22 per cent. of solid matter—18 of which is nitrogenous. They want butter, therefore, to increase their nutritive value.

Mackerel, *eels*, and *salmon*, are, however, richer in fat, for the former contains about 7 per cent. and the latter 6, while the oily matter of eels amounts to nearly 14 per cent. The same is the case with the sprat, the herring, and the pilchard, and with most of our fresh-water fish.

All fish are in their best condition at the time of the ripening of the milt and roe, for not only are they fatter at that time, but when cooked they have a better flavour, and the flesh is solid and opaque. On the other hand, when they are out of condition the flesh is semi-gelatinous and watery.

Shell-fish of all descriptions have nearly the same nutritive values. They contain about 13 parts of solid matter in the hundred, and this has the composition of white fish. Their digestibility varies—*mussels*, *limpets*, and *whelks*, being rather hard of digestion, while *scallops*, *cockles*, *periwinkles*, *lobster*, and *crabs*, are, perhaps, a little more easily digested, and *oysters* still more so. None of them are suited for delicate stomachs, although the poorer inhabitants on the coast eat them freely; and vineyard snail on the Continent, and even *slugs* in China, have a reputation for delicacy and nutritive power.

Eggs contain about 26 per cent. of solid matter, 14 of which is nitrogenous, and 10½ carbonaceous or fatty. The *yelk* is the part which contains the fat, for it there amounts to nearly 31 per cent., while the *white* of the egg, which is entirely free from fat, is the richest in nitrogen—the albumen amounting to 20·4 per cent. Altogether, however,

eggs are very deficient of carbonaceous matter, for, calculated as starch, it is only in the proportion of 1·75 to one of nitrogenous. Hence it is that eggs consort well with oil in salads, with fat bacon, and with all kinds of farinaceous matters in puddings.

Fat of some descriptions—as *butter*, *lard*, *suet*, or *dripping*, is universally consumed. In many cases it exists in sufficient quantity in the food, as in bacon and fat-meat, but when this is not the case, it is invariably supplied from some other source. 99 per cent. of farm labourers use fat of some sort—butter or dripping, to the extent of 5½ ozs. weekly per adult. It is difficult to say how much is really required by the human system, but looking at the proportion in milk, it would seem to be not less than 28 per cent. of the dry solid food. The fats in common use contain about 80 per cent. of real fatty matter, the rest being water and salt, and although butter is the fat ordinarily purchased, yet dripping is equally valuable, and so also are the vegetable fats of the tropics. *Cocoa* and *chocolate* owe their chief value as foods to the fat they contain. Cocoa is composed of 50 per cent. of solid fat, called cocoa butter, and chocolate is a sweet preparation of it.

Of liquid articles of diet, *beer* and *porter* stand first in nutritive value. They contain about 9 per cent. of solid matter, 8¾ of which are sugar and gum. Their nutritive power is not, therefore, great; and yet, according to Liebig, whenever beer and porter are not used, there is always a larger consumption of bread.

The nutritive functions of *tea* and *coffee* are hardly understood; for although they are largely used, and as if by an instinctive craving, yet their actual nourishing power is insignificant. I shall deal further with this subject hereafter.

The last constituent of food that we have to consider is saline matter. Broadly, it may be stated that we require *phosphates* and *sulphates* of *potash*, *lime* and *magnesia*, and that we also want a still larger proportion of *common salt*. In most cases the phosphates and sulphates are in sufficient quantity in ordinary foods; in fact, Mr. Lawes found in his experiments on the fattening of animals that for every single part of saline matter retained in the system of the pig, there were from 14 to 15 parts in the food; not that the whole of this was lost, for probably it performed important functions in the processes of assimilation and secretion. Common salt, however, is not present in the food to any large extent, and, therefore, it must be added to it.

And now, before leaving this part of the subject, let us pause to consider the vast machinery which is in operation to supply the food to this metropolis. At the present time over three millions of people have to be daily fed; and yet so regular is the supply that no one considers even the possibility of its failing. On the other hand, there is no redundancy; and not only does this supply regularly reach the metropolis, but it is distributed to our very doors. About 4200 tons of fish; over 4000 sheep; nearly 700 oxen; about 90 calves; 4000 pigs, including bacon and hams; not less than 5000 fowls, and other kinds of poultry; besides a million or so of oysters; and eggs innumerable, with flour enough to make nearly a million quartern loaves: and vegetables, butter, and beer in proportion, are daily brought to this city. "Imagine," as Archbishop Whately says, "a Head Commissioner entrusted with the office of furnishing all these things regularly to the people. How would he succeed?" And yet all this goes on with the regularity and precision of a machine—without Government or even municipal interference, but simply through the magical power and unfettered action of free trade.

The lecture was profusely illustrated with specimens of foods from the magnificent collection in the Economic Museum of Mr. Twining, who kindly lent them for the occasion.

Original Communications.

ANATOMICAL NOTES.

By ALEXANDER MACALISTER, L.R.C.S.,
DEMONSTRATOR OF ANATOMY, ROYAL COLLEGE OF SURGEONS, IRELAND, SURGEON TO THE ADELAIDE HOSPITAL.

I.—VARIATIONS OF THE RECTUS FEMORIS MUSCLE.

It is a general rule, from which there are but few departures, that muscles which have a definite unvarying action are the least liable to abnormal arrangements; but we find a few exceptions in the cases of those parts which in lower animals exhibit different and variable appearances, unlike the conformation of the normal human type. Among these the rectus femoris holds a prominent place, for, though always developed as an extensor of the knee, its absolute point of origin is occasionally the subject of variety in the animal kingdom. In man we find it to be constant in its position and direction, and usually invariable in one of its origins, namely—that from the anterior inferior iliac spine. Its curved or reflected origin may vary in length from half-an-inch to an inch and a-half, or even two inches and a-quarter; it may be completely continuous in point of origin from the spine of the ilium to the acetabular notch, exhibiting no sign of an interval, or the heads may be separate for an extent double the ordinary interspace. The curved origin may be above and unconnected with the capsular ligament of the hip, it may arise inseparably united to that ligament, or it may spring from the bone betwixt two laminæ of the ligament. The more singular deviations which I have met with are, first, the existence of a supernumerary straight origin in the form of a fibrous band springing from the anterior superior spine of the ilium. I have seen this twice—in one case as a weak fascial slip, in the other as a strong tendon; the second is the existence of a supplementary band to the curved head, which, starting from a point on the outer edge of the anterior surface of the femur about an inch below the summit of the great trochanter and in contact with the origin of the vastus externus in the situation of the rarely developed third trochanter, ran inwards and upwards, to be connected with the curved head very near its commencement; this slip thus formed an angle of 135° with the curved head, and it crossed the capsule of the hip-joint to which it had no connection. It was covered by the anterior border of the gluteal muscles, and acted as an accessory ligament of the hip somewhat similar in direction to the superior ilio-femoral accessory of Humphry, which was otherwise deficient in this subject.

The rectus femoris is homotypical with the long head of the triceps extensor cubiti; and the latter presents us often with a duality of origin nearly as distinct in degree as that of the rectus. I have seen it connected with the inferior gleno humeral ligament, a condition exactly accordant with the lower extremity arrangement just noticed.

II.—DOUBLE URETERS.

In a subject which I dissected within the past session, 1866-7, two ureters started from the left kidney, coalescing after a course of two inches, into one tube, which was normal in its course.

III.—VARIATIONS IN THE BRANCHES OF THE ABDOMINAL AORTA.

One subject dissected by me in the Royal College of Surgeons Anatomy Hall, during the session 1865-6, exhibited the following peculiarities:—The gastric artery came off as a separate branch from the aorta, but soon gave off a small right division, which passed in the layers of the gastro-hepatic omentum to the left extremity of the portal fissure of the liver; the other branch was normal; the cœliac axis, arising directly below the gastric, but separated from it by the upper connecting fibres of the solar plexus, divided into two the hepatic and splenic vessels, which were normal in course and distribution; lastly, the superior mesenteric artery, which arose at the root of the

cœliac axis in passing downwards in front of the pancreas, gave off a large hepatic vessel, which entered the right extremity of the transverse hepatic fissure.

The arrangement of the cœliac axis in this case is similar to that noticed by Flood, and the position of the origin of the superior mesenteric is nearly the same as in the instance recorded by Geddings, who has also noticed the origin of the gastric as a separate trunk, along with the phrenics, an arrangement which did not occur in this instance. The origin of an accessory hepatic artery from the two abnormal sites noticed above, has been already described, but it is a singular fact to find the occurrence of so many varieties in a single region.

In another subject, three renal arteries, branches of the aorta, supplied the left kidney, one above and one below the normal sites, the upper and lower going into the extremities of the gland.

IV.—VARIETIES OF ARRANGEMENT OF THE HEPATIC LIGAMENTS.

The folds of peritoneum so called, may vary in position. Thus, in one instance, a young boy, about 15 years of age, the left lateral ligament was attached to the abdominal wall, in front of the spleen, which it covered, and to which it formed an anterior relation. The point of attachment was opposite the level of the cartilage of the tenth rib. In this subject the œsophagus lay directly behind the coronary ligament, which was unusually extensive, and was accommodated by a special groove in the thick edge of the liver. The liver was but slightly enlarged, and lay much nearer the middle of the abdomen than usual.

V.—VARIETIES OF THE SUPERIOR THYROID ARTERY.

This vessel was absent in one subject on both sides, its place being supplied by a large inferior thyroid. This variety was observed by Quain. In another instance, an old female, the artery arose from the common carotid four lines below the point of its bifurcation, and passed inwards, giving off only a superior laryngeal branch and its terminal vessels to the thyroid body. No hyoidean nor sterno-mastoid branches existed, but the place of the latter was supplied by a branch of the occipital, and the inferior or crico-thyroid branch was only present on the right side. The same subject had the facial and lingual arteries arising by a common trunk, and the latter was extremely long and tortuous. The inferior palatine and tonsillitic arteries arose by a separate trunk from the external carotid, beside the origin of the former, and on the right side the occipital and posterior auris were united for about an inch.

VI.—ABNORMAL POSITION OF THE PNEUMOGASTRIC NERVE.

In the neck of an old female, on the right side, the carotid artery presented a sharp flexure, about an inch and a-half below its bifurcation. Over this the pneumogastric nerve crossed, at first from without inwards, and then crossing again completely to the outside. That this was the actual condition of the vessel during life was evident, as the nerve was connected to the anterior surface of the artery by a process of the sheath, and could not be replaced in the usual position until the connecting bands of the sheath had been divided. The importance of the knowledge of the possibility of this occurrence is very great, as it might lead to a serious complication in the operation of ligature of the carotid artery.

NOTES OF A CASE OF TUMOUR OF THE NECK.

By JOHN STUART VESEY, M.D., F.R.C.S.I.,
MEDICAL OFFICER TO THE MAGHERAFELT UNION INFIRMARY, ETC.

Rose Magill, aged 17, of fair complexion, was admitted into the Magherafelt Union Infirmary, with a tumour the size of the clenched fist occupying the left side of the neck. States that three years before admission she was affected with a sore throat, from cold, which she neglected; at this time the glands on both sides of the neck were enlarged and moveable. These disappeared, except one on the left side, which continued gradually to enlarge without pain. Says she often used to touch them with her fingers, but did not apply for any relief for the first year. At the end of that period she applied an ointment of a brick colour, which irritated the skin and caused it to desquamate; it became more moveable, but still increased in size.

The tumour extends downwards and forwards along the side of the neck, of an oval shape, the base below reaches within about two inches of the sternum. Its upper extremity was within an inch and a-quarter of lower part of the ear, and immediately behind the angle of the lower jaw, and appeared to run very deeply. Its posterior margin bounded by the sterno-mastoid muscle, and external jugular vein, its anterior rested near the larynx. The integuments were not discoloured. The tumour was quite moveable under the integuments, except its neck, which seems very deeply fixed. It had a firm feel and slightly elastic. The carotid artery could be felt under it towards its anterior margin. There is no difficulty of breathing or swallowing.

An oblique incision was made downwards and forwards over the long axis of the tumour to the extent of nearly three inches; its upper end was immediately in front of the vein, and close to the angle of the jaw; its lower extended to within about two and a-half inches of the sternum. The skin, &c., being divided, the tumour was cautiously dissected, and its lower part and sides were removed first, the knife being kept close to the tumour. The tumour at the same time was pulled out. The neck ran very deep, and was with difficulty removed. She lost about three ounces of blood, but no artery required ligature. There was some venous hæmorrhage from the lower part, which was stopped by a pressure.

The operation was very tedious. She got somewhat pale, but bore the operation well. Two points of interrupted suture were applied, and strips of adhesive plaister, and a compress at either side of the incision, and a bandage over all.

Evening of operation.—Great thirst; considerable pain in the neck; bowels not opened, but they had been well evacuated two days before the operation.

Day after the operation.—Slept none; pain; some swelling and redness in the neck; bowels not moved. Ord.—Lint stuped in water, with the cold off it, to the neck.

Ext. colcocynth. comp. gr. v. every fourth hour. Enema. Haust. ol ricini.

Pulse 104; some thin, sanguineous discharge since the operation.

2nd day.—Removed the sutures; union seems about to take place; some discharge; rests on sound side, with head elevated; bowels well moved and pyrexia relieved.

3rd day.—Doing well; dressed with adhesive plaister, lint, and bandage daily; swelling less; the discharge comes from two points; lips not quite united, but the bottom of wound seems to be so.

In about three weeks after the operation she was able to go home; the wound entirely healed; nothing remains but a narrow red cicatrix, the upper part of which can scarcely be perceived.

Appearance of tumour.—It was entirely surrounded by a thin, firm cyst, which adhered closely to it; loosely attached to it was a gland near the size of the end of the thumb.

On dividing the tumour, it was of a dirty white colour, slightly convoluted, something like the brain, and very firm to the feel.

Hospital Reports.

ST. GEORGE'S HOSPITAL.

A YEAR'S SURGICAL PRACTICE.

(Continued from page 115.)

Diseases of the Organs of Circulation.—One case of *disease of the heart* in a man aged 40, was admitted; he had suffered from intense pain down the arm as far as the

elbow for some time ; it had come on without any assignable cause ; was somewhat paroxysmal in character, and was also intermittent, acquiring its greatest intensity at about three o'clock every afternoon. Quinine was ordered. The pain continued unrelieved ; and, as there was no morbid appearance in the arm, he was transferred to the medical wards. Two days afterwards, he was seized with strong convulsions and died. The heart was uncontracted, flabby, and empty : on its anterior surface was a small mass of firmly-adherent lymph. There were large vegetations on the aortic valves ; the mitral valve was blood-stained, and studded with slight fibrinous deposits. The orifices of the coronary arteries were healthy. There was tubercle in the lungs, and the bronchi were full of purulent fluid. Tubercular matter was also found in the kidneys, ureters, bladder, and prostate.

Two cases of *aneurism* were admitted. One of these was traumatic. A week previously, the patient had been cutting broom on a common, when his knife slipped and wounded him in the leg. Hæmorrhage ensued, arrested by a tight bandage, and the wound nearly healed. On exerting himself, the bleeding recurred. When admitted, there was a punctured wound over the inner head of the gastrocnemius muscle, on a level with the inner tuberosity of the tibia. Just below the wound was a pulsating swelling, about the size of a pigeon's egg. The swelling continued enlarging, and was evidently connected with one of the muscular branches of the popliteal artery. A needle was passed beneath the vessel leading to the tumour, and pressure made by means of an elastic band attached to either extremity of the needle, passing over a cork which was placed between the needle and band. The pulsation in the aneurism immediately ceased. Beyond slight pain, no inconvenience followed this operation ; the cut, and the punctures made by the needle readily healed, and in about three weeks the patient was discharged well ; the tumour was less than a third its original size, and was being rapidly absorbed. The other case was transferred from the medical wards, having been supposed to be a case of caries of the spine, which it closely simulated. The man was aged 30, and was admitted with the history that, four years previously, he had fallen a height of fifteen feet. He suffered very little from it till twelve months before admission, when he began to suffer pain in his back. Latterly this had been accompanied by shooting pains in the legs, with twitching of the muscles and cramp. When admitted, there was tenderness on percussion over the last lumbar vertebra and upper part of the sacrum. In the left inguinal region there was a hard swelling, simulating a psoas abscess. After rest in bed for a month the swelling diminished slightly, but the pain became more intense. He was suddenly seized one day with extreme faintness, and died. At the post-mortem examination there was found to be a large quantity of blood in the peritoneal cavity. In the left lumbar region, and extending down into the left iliac fossa, was an enormous aneurism, which was situated behind the left kidney and descending colon : the sac of the aneurism was incomplete behind, the posterior wall of the cavity being formed by the bodies of the vertebræ and lower ribs, which were exposed and eroded, and were in direct contact with the blood in the sac. The sac was full of coagulated blood ; and on its anterior aspect had a lacerated opening about an inch in length, through which the blood had been poured into the peritoneal cavity. The walls of the sac did not appear to be formed of the coats of the aorta, but simply of consolidation of surrounding structures. It communicated with the abdominal aorta by a rounded opening, the size of a shilling, on its posterior wall. On passing the finger through this opening, it immediately came down on exposed bone. The bone in the left iliac fossa was exposed, but the sacro-iliac joint was sound.

Two cases of *nævus* occurred in infants. One, which was situated at the back of the neck, was destroyed by nitric acid ; the other, an inch in diameter on the back, was removed by subcutaneous ligature.

Thirty-one cases of *varicose veins* of the lower limbs were admitted. Of these, a large proportion were complicated with the so-called varicose ulcers. In twenty instances the vessels were obliterated by subcutaneous section, and a permanent cure effected. In the remaining cases the support of an elastic stocking was thought more advisable.

In one instance a clot in a varicose vein formed a tumour rather larger than a walnut, on the inner side of the right leg. It was situated in the course of a large vein, which could be felt entering and leaving it on drawing the tumour upwards and downwards—by which means the vessel was put upon the stretch, and could be felt as a hard cord connected with the tumour. It was dissected out under chloroform.

Five cases of *phlebitis* occurred. In two of these a needle was passed beneath the inflamed vein, and the disease arrested ; suppuration occurred below the needle, whilst the parts above remained healthy. One case, in which the deep veins of the right lower limb were affected, proved fatal. There was no post-mortem examination.

Of diseases of the *lymphatics*, thirteen were cases of inflamed *absorbents*, twenty-four of *suppuratiny glands*—many of which were venereal—and two of *tumours of glands*. The nature of one of these was uncertain ; the other was a case of scrofulous infiltration of the cervical glands, and proved fatal.

Diseases of the Respiratory Organs.—Among these were four cases of *disease of the larynx*. In one of these, in which the affection was of a syphilitic nature, laryngotomy was performed. In one case the patient, a woman aged 48, had suffered from pain and difficulty in swallowing for a twelvemonth ; and for six months she had been unable to swallow solids. On examining the epiglottis with the finger, it was felt to be much enlarged, and roughened on its posterior surface. During deglutition, there was greater pain referred to the neighbourhood of the epiglottis than was experienced when it was touched. The alæ of the larynx appeared to be rather widely separated, and were tender on pressure. There were several enlarged and very hard glands near the angle of the lower jaw on the left side ; the patient had a malignant aspect, both from emaciation and discolouration of the skin. She was discharged as incurable.

(To be continued.)

COOMBE LYING-IN HOSPITAL.

OPERATION FOR VESICO-VAGINAL FISTULA.

By Dr. KIDD.

On 22nd January we had an opportunity of seeing Dr. Kidd operate in the chronic ward of the Coombe Lying-in Hospital, Dublin, for a large vesico-vaginal fistula. The patient, who came from the neighbourhood of Tralee, had been delivered of her second child about five months before. The child had presented by the lower extremities, and after the trunk and arms had been expelled the head remained in the vagina for more than twelve hours, whilst aid was being obtained from Tralee. On the 5th day after delivery a large slough was expelled from the vagina, and the woman has had incontinence of urine ever since. Dr. Kidd placed her lying on a table in the semi-prone position described by Sims, and having brought her completely under the influence of chloroform, introduced the duckbill speculum, and brought a large fistula fully into view. It extended from near the commencement of the urethra to the os uteri, was of an oval figure with the long axis running obliquely from the left side of the os downwards, and to the right, and was an inch and a half long by one and a quarter broad. The upper border was formed by the uterus, and a very narrow rim of the vaginal septum, with the mucous membrane of the bladder swollen and prolapsed. The lower border was drawn into the bladder and hidden from view by a lunated fold, formed by the puckering of a cicatrix.

The operation was performed by first paring the vaginal mucous membrane for half-an-inch in breadth, off the cervix of the uterus, where it formed the upper edge, and then to the same extent round the remainder of the opening, special care being taken to remove it from all the folds formed by the contracted cicatrix. When it seemed necessary in order to secure the correct co-aptation of the edges, the cicatricial bands were freely divided. The edges were now brought together by iron-wire sutures, passed at the upper part, by means of one of Weiss' laterally curved tubular needles, and in the remainder by the plain tubular needle. The sutures were placed within an eighth-of-an-inch of one another, and when necessary they were passed right through the anterior lip of the uterus. In bringing the edges together Dr. Kidd used neither adjustors, plates, buttons, nor splints ; he adjusted the edges, and twisted the sutures with his fingers, stating that he found he could judge much more accurately in this way of the tension of the suture, and the amount of pressure exercised on the edges of the wound. The patient was now removed to bed, and a morphia suppository introduced into the rectum, a gum elastic male catheter passed into the bladder and secured there by a T-shaped bandage. This catheter was of a large size, and had two eyes at a little distance from one another, so as to lessen the risk of its being obstructed by clots, or of its allowing water to accumulate in the bladder.

On the 31st January, the tenth day after the operation, we had again an opportunity of seeing this patient, when Dr. Kidd for the first time introduced the speculum, and examined the wound. The edges were in perfect apposition and seemed thoroughly united, but as there was no irritation from the sutures Dr. Kidd did not remove them, and, as the catheter did not cause any annoyance, he directed that it should still be kept in the bladder.

Summary of Science.

(Specially Edited and Compiled for the Medical Press and Circular.)

By CHARLES R. C. TICHBORNE, F.C.S.L., F.R.G.S.I., Etc.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

METHYLIC ALDEHYDE.

THE aldehyde of the methylic series has never been procured, although a substance of considerable chemical interest. One of the latest investigations of Dr. Hofmann has been on this important body, and with his accustomed success, he seemed to have formed this substance or a prolimeric compound. He covers the bottom of a strong three-necked bottle with methylic alcohol. The first neck is provided with a tube descending to the very surface of the liquid. Into the second is fixed a loosely fitting cork, which carries a platinum spiral wire. The third one, communicates with the upper end of a condenser, the lower end of which is fastened into a two-necked receiver. This receiver is again connected with an aspirator, by which a current of air is kept up through the whole apparatus. The platinum spiral is heated to redness and introduced into the three-necked bottle. In a few minutes a flameless combustion of the methylic alcohol begins to manifest itself by the evolution of a vapour, which powerfully affects the nose and eyes. The liquid which collects in the receiver has all the properties which theory assigns to the aldehyde of the methyl series.

Dr. Hofmann has prepared the sulphaldehyde by passing sulphuretted hydrogen through this liquor, *i.e.*, the solution of methylic aldehyde in methylic alcohol. On adding hydrochloric acid, white crystals were formed, which give, on analysis, CH^2S.

TRANSFORMATION OF THE AROMATIC ACIDS IN THEIR PASSAGE THROUGH THE ANIMAL ORGANISM. FROM A FRENCH MEMOIR. BY M.M. GRAEBE AND SCHULZEN.

The authors, after having taking two grammes of chlorobenzoic acid in the evening, examined their urine the following morning, and found it to contain chlorohippuric acid, identical with that which M. Otto obtained by the action of chlorine upon hippuric acid.

Anisic acid on traversing the economy is transformed into anisiuric acid $C^{10}H^{11}NO^6$. Under the same circumstances, cinnamic acid is converted into hippuric acid. The same results were got with amydalic acid.

Phtalic acid is transformed into a body containing nitrogen, which is very soluble in water. It has not been obtained in a quantity sufficient to be studied.

Tyrosine passes in the organism without altering. It was re-found in the urine.

BENZOIC ACID.

According to Dr. Odolfotts, benzoic acid is now largely manufactured, commercially, from napthaline (a waste product from the manufacture of gas, which, hitherto, has received no application, although procured in large quantities). The benzoic acid is got by a rather complicated and laborious process, but from the great cheapness of napthaline, it can be manufactured for the market. It is said that it is the most important discovery made in technical chemistry since the London Exhibition of 1862.

DETERMINATION OF COPPER.

M. Lecoqe de Boisbaudran separates this meta l in the following manner :—The slightly acidulated solution of the sulphates of copper and other metals is placed in a platinum crucible, which forms the negative current from two of Bunsen's cells. The positive pole terminates in platinum foil, and passing through a perforation in a watch-glass, which covers the crucible, dips into the liquor. The copper separates in a perfectly pure state, and the reduction is accomplished in three or four hours.

MELILOTIC ACID.

This acid is found in *melilotus officinalis* combined with curmarin. It belongs to the salicylic series, and, when fused with hydrate of potash, hydrogen is evolved, and salicylic and acetic acids are formed. This acid is monobasic, and its salts mostly crystallize well.

ESTIMATION OF LEAD BY PRECIPITATION IN THE METALLIC STATE.

M. Stolba estimates the lead (either in soluble or insoluble compounds,) by zinc, in the presence of hydrochloric acid. The reduction is made at a temperature of a salt-water bath, and in a platinum crucible. As lead is soluble in pure water, the spongy precipitate obtained is washed with common water acidulated with a few drops of sulphuric acid. This lead, when dry, does not give exact results on weighing, because the surface is partially oxidized ; it is therefore better to estimate it volumetrically by Mohr's method, namely—by dissolving in a volumetric solution of nitric acid, and afterwards tritrating the excess of acid by a solution of soda.

ACTION OF ALDEHYDE ON ANHYDROUS PRUSSIC ACID.

Dr. Maxwell Simpson and A. Gautier describe a substance got by the prolonged action (10 or 12 days) of anhydrous prussic acid and aldehyde—molecule for molecule. They gradually unite, and on submitting it to fractional distillation, the greater part passed over about 183C. They propose cyanhydrate of aldehyde, as a name for this compound, which is simply founded upon its synthetical formations.

Gaseous ammonia is absorbed by this body with the production of a body, not yet analyzed. Treated with hydrochloric acid in a freezing mixture, an acid was obtained, which, on analysis, proved to be ordinary lactic acid.

The authors conclude by saying, that their experiments afford a striking example of an organic body, which is disassociated by heat, and reconstructed by time.

THE FABRICATION OF CARBONATE OF SODA.

Salt is intimately mixed with sesquioxide of chromium only, or with the addition of oxide of manganese, or with chromate of iron or lead. This mixture is heated to about a red heat, and is then submitted to a current of steam. Hydrochloric acid and chromate of sodium is thus produced. When the disengagement of hydrochloric acid has ceased, the fire is decreased, and the whole is mixed with charcoal and again warmed to a sombre red heat. The chromate of sodium is by this means transformed into carbonate of soda and sesquioxide of chromium, which can then be used indefinitely. It suffices to submit the product of this second calcination to a regular washing, to separate the two substances.

ON THE PREPARATION OF MICROSCOPIC CRYSTALS.

Mr. Waddington, in a communication to the Pharmaceutical

Society, says that it may be laid down as a definite rule, that the formation of perfect crystals depends upon the rapidity with which they are deposited ; the more quickly the solution can be made to crystallize, the more perfect the crystals generally are. (These remarks, of course, appertain to crystallizing upon microscopic slides alone.—E. S.)

The exceptions to this rule are very soluble substances, such as sugar, tartaric, and citric acids. In such cases the author recommends cold saturated solutions, and to leave thin layers of these solutions to dry in the air. In a damp atmosphere, they will not crystallize at all. Herapathite (sulphate of iodoquinine) should be mounted dry, if it is desired to preserve it as a permanent object.

ACTION OF PEROXIDE OF MANGANESE ON URIC ACID.

If uric acid and peroxide of manganese are heated together with water and sulphuric acid, a quantity of large hexagonal crystals are formed, which consist of parabanic acid. If, however, says Mr. C. Wheeler, the uric acid is heated with a large quantity of water and peroxide of manganese added, as long as carbonic acid is evolved—urea, allantoin, and oxalic acid are formed. The action of peroxide of manganese upon uric acid resembles, therefore, very closely that of peroxide of lead.

MOCK SCOTCH SODA CRYSTALS.

These are, properly, sulphate of soda. It is, however, difficult to tell them from Scotch soda (washing soda of the shops,) by the eye alone.

Twelve pounds of soda ash are added to every hundred pounds of the sulphate of soda in solution. The liquid is allowed to settle, and then drawn off into coolers to crystallize.

ACTION OF HEAT UPON SUGAR, ETC.

Cane-sugar is decomposed when heated with water in sealed tubes to 160° C. Carbonic acid gas is formed, and carbon separates the latter, amounting to nearly half the quantity of sugar taken. The contents of the tube show strong reaction due to formic acid. A small quantity of ulmic acid is also formed. No decomposition takes place if sugar is heated with alcohol to the same temperature, or with a solution of baric hydrate. Other members of the sugar group treated in this manner show a similar behaviour. The action of water on gum gives rise to the formation of a new acid which is insoluble in water, but soluble in alcohol and ether.

ON THE PREPARATION OF NICOTINE. BY M. PHIBRAN.

The author digests with heat for twenty-four hours 3 kilogr. of leaf-tobacco with 10 litres of water acidulated by 90 grammes of sulphuric acid. The filtered liquid is evaporated to a thick consistency in a salt water bath—having added to it 125 grammes of pulverised charcoal to prevent the mass from agglutinating. The residue is dried by a gentle heat, and then powdered and digested during twenty-four hours with three times its weight of hot alcohol at 90 centiemes. He distils this alcoholic tincture, and redissolves the residue in water. A brown watery liquor is thus obtained, which contains all the nicotine, and, at the same time, some sulphate of ammonia. He again distils with an excess of potash, and saturates by sulphuric acid the distilled liquor. After decolourising it, the author evaporates by a salt water bath, and treats the dry residue by absolute alcohol, which dissolves all the sulphate of nicotine. The alcohol having been distilled off, the nicotine is set free by potash, and he shakes the resulting liquor with ether, which rises to the surface, and forms a distinct layer containing all the nicotine. This layer being decanted, leaves the nicotine, after the evaporation of the ether.

PYROGALLIC ACID.

M. M. Victor de Lunes and Esperandieu, make this acid in the following manner :—They introduce into a bronze vessel, which can be perfectly closed, gallic acid with two or three times its weight of water, and maintained at a temperature of 200 to 210 degrees during an hour and a half or two hours. The boiler then contains a slightly coloured solution of pyrogallic acid. It is boiled with animal charcoal, and after filtering is evaporated. On cooling, the pyrogallic acid crystallizes in a hard mass of a light brown colour, or slightly tinged rose colour. To obtain it perfectly white, it may be distilled in a vacuum. By this process the theoretical quantity may be got from the gallic acid.

When a solution of pyrogallic acid is added to lime water, a magnificent violet colour is produced. Ethylamine produces the same reaction.

When a concentrated and slightly acid solution of sulphate of quinine is mixed with a concentrated solution of pyrogallic acid a crystalline and slightly yellow deposit is formed, which contains the elements of sulphate of quinine and pyrogallic acid. When perfectly bright solutions are mixed, no precipitate is formed until a crystal of sulphate of quinine is added, when it becomes nearly solid.

ATTAR OF ROSE.

The author confirms the opinion of which many pharmacologists have long been perfectly aware, that commerce at the present day knows of but one source for Attar of Rose worth naming, and that is the southern slopes of the Balkace.

According to some authors, the rose which is used for making Attar is Rosa Moschata. According to others, R. sempervivens, R. centifolia, R. provincialis, or R. damascena. The author's opinion is, that the original rose, which has been long in cultivation there, is a variety of R. damascena, and in this opinion he is supported by Professor Hugo *v.* Mohl. The resin of the calyx which adheres to the knives and hands of those who cut the flowers, is collected and prized as a perfume under the somewhat inappropriate name of "Gül Schamur." (Rose dirt).

The nature of the soil has an influence, in so far as that, when it is poor in humus, and but seldom manured ; the roses afford but little oil, and that more congealable, or in other words, richer in stearoptene. Pure attar of rose, carefully distilled, is at first colourless, but speedily becomes yellowish. Its sp. gr. at 18° R. 72·5° Fahr. is 0·87, its boiling point 229° C. (444° Fahr). It consists of an elœoptene and a stearoptene, the former the source of the odour, the latter of the property of congealing into a solid form. Pure attar of rose, once distilled, solidifies at a temperature of from 11° to 16° C. (51·8° to 60-8° Fahr), or still higher—it is soluble among other things in absolute alcohol, and in acetic acid. Its odour is rose like, with a peculiar honey like sweetness, agreeable only when highly diluted. The most usual and, by long practice, also the most certain criteria of the purity of attar of rose are—

The temperature at which it congeals.

Its manner of crystallizing.

Its odour.

In Kezanlik, as at all other places, attar is, up to the present time, bought and sold, chiefly according to the temperature at which it solidifies, in other words, according to the proportion which it contains of inodorous camphor or attar of rose steroptene. Why is this ? the answer is simple. The stearoptene is, to a certain extent, one of the constant constituents of attar of rose, and an indicator of its purity. If rose oil be augmented by fradulent additions, its congealing point will be thereby diminished, and it will be necessary to produce its crystallizing tendency by the addition of some substance possessing properties like those of natural stearoptene. But any such body, which is not at once recognisable, even by a person of small experience, does not, to the author's knowledge, exist. If the mixture of spermacete is proved, there is still the question of adulteration with essential oil, and this is, in fact, much more frequent, and also of much more difficult recognition. The admixture in question relates entirely to the so-called geranium or palmarosa oil. The oil of rhodium and oil of sandalwood, are, indeed, with attar, as stated in many handbooks of materia medica, or that such a mixture could be substituted for pure rose oil, is, for any person who has once in his life smelt these oils, simply an impossibility. The Turkish geranium oil (in Turkey, called enterschah) is, according to accounts, derived from a grass of the genus Andropogon, which is distilled in the months of December and January, in the neighbourhood of Delhi. The author has learnt to distinguish but one constant character for geranium oil, which is that of not diverting a ray of polarized light, whilst attar, in the tube of 100 m m, rotates the ray 4° to the right. Here is the single handle for the examination of a suspected attar. Considerable difficulties are certainly in the way of using such a test. The differences observable are very small, and the test is, in fact, applicable only in the case of very gross adulteration. The author considers that in attar of rose, which at a temperature of 12-5° C. (54'5° Fahr.) in a thin glass tube, does not congeal well in the space of five minutes, and which has not moreover a dextrogyre rotatory power of 4°, should be returned to the seller, no matter how fine may be its odour. That there are attars which solidify at 10° C. (50° Fahr.) and yet are genuine (owing, for instance, to faultily conducted, or to repeated distillation), is just as true as that there are those which do the same, at from 20° to 25° C. (688 to 77°

Fahr.) and are yet of indubitable goodness—but these are exceptional, as in the case of opium, certain indubitably pure samples of which have yielded respectively 2 and 16 per cent. of morphia.—(From a translation by Daniel Hanbury—the author being R. Baur, of Constantinople.)

Foreign Medical Literature.

REPORT OF AN OPERATION FOR HERNIA CEREBRI: WITH OBSERVATIONS.

BY DR. MED. H. HIRSCHSPRUNG.

Translated, with abridgment, from the *Ugeskrift for Læger*, Nos. 16-19, March and April, 1867.

By W. D. MOORE, M.D.Dub. et Cantab., M.R.I.A., L.K.Q.C.P.I.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS; OF THE NORWEGIAN MEDICAL SOCIETY; AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; SECRETARY FOR SWEDEN, NORWAY AND DENMARK, TO THE EPIDEMIOLOGICAL SOCIETY OF LONDON.

(Continued from page 70.)

Scarcely fourteen days after the operation, however, consequently long before the healing of the incision in the skin, decided signs of a complication presented themselves, which, notwithstanding that the child's general condition was in no way affected thereby, was too well calculated to obscure the favourable prospects which at first seemed to open, of its recovery. In the increasing width of the sutures and fontanelles, we had unmistakable signs that a collection of fluid had begun to form within the cavity of the cranium, and measurement of the head, repeated at different periods, proved that the amount of fluid was rapidly increasing.

Thus, in the course of seven weeks, the horizontal circumference of the head had increased by not less than four inches, and other measurements had grown in the same proportion. The head had gradually acquired the high, arched, and projecting forehead peculiar to hydrocephalus, which stood in marked contrast to the small face; the skin of the head had become tense and shining with translucent veins, the fontanelles were bulged convexly forwards, the feeling of fluctuation could be communicated from one to the other; the sutures, both great and small, become more and more widened, the child had difficulty in holding its head erect, and inclined it now to one, now to the other side. But at the same time its appearance was that of a very thriving child, and all its functions were in the best order. There was no paralysis, sometimes there was slight strabismus, but not more than in so many infants who have not yet learned to fix objects correctly, and the pupils were natural. Latterly, the child showed some signs of beginning to take notice, evidently listening to various sounds, and looking after things held before its eyes, although with an uncertain look. I shall further call attention to a circumstance which might indicate that the right half of the brain was more deeply implicated in the hydrocephalic process than the left: through the highly dilated anterior fontanel, the falx cerebri was distinctly felt as a resisting cord, lying, not in the middle, but a couple of lines to the left of it. The comparative measurement of the lateral portions of the head did not, however, afford a result tending in the same direction, on the contrary a slight difference ($\frac{1}{8}''$) was found in favour of the left side.

The state of affairs could not be mistaken. It was evident that the sac adherent to the head, had been the receptacle for a copious secretion of fluid within the cranium, which must have been going on long before birth, the operation had prevented the escape of the fluid, and the latter was now dammed up, and endeavoured to get room by extending its boundaries. After the operation had removed the external appendix, and as the loss of the small prolapsed part of the brain seemed unattended with any serious consequences, the remaining affection was to be classed with the ordinary congenital hydrocephalus, of which it shared not only the symptoms, but also the prognosis and treatment. The prospect must certainly be looked upon as bad, but still treatment ought not to be neglected. With Bednar's experience before me: ("I have in some cases seen congenital hydrocephalus get well under the use of iodide of potassium, *Lehrb. der Kinderkrankh*, 1856, p. 160), I tried iodide of potassium first without, subsequently in combination with compression, as it was my purpose, if these means failed, to try puncture through the anterior fontanel, or perhaps through the opening in the cranium, through which the hernia had protruded.

On the 4th April, I began the employment of iodide of potassium, with a solution of half a drachm to eight ounces, of which the child took a tablespoonful three times a-day, but by degrees I increased the daily dose to double. The medicine showed its action by a slight catarrhal affection of the mucous membrane of the eyes and air-passages, the flow of urine was increased, and the alvine discharges gradually became thinner and more slimy, but the child's general health continued satisfactory. On the 8th of May $3\frac{1}{2}$ drachms of the iodide had been taken. The urine was light-coloured, clear, neutral, free from albumen; by Heller's xyloidin-test it exhibited a strong reaction of iodine. The head continued to expand, though more slowly than before. Immediately beneath the occipital cicatrix an oblong depression in the bone was felt, which was driven a little forward when the child cried. The degree of strabismus was variable. During the use of the iodine, compression with adhesive plaster over the whole head, was employed on the 10th of May. This plaster, showing a tendency to separate, and there being also some eczema of the scalp, and slight ulceration of the cicatrix, was removed on the 12th June. The increase of the measurements of the head was considerably less than during the use of the iodine without compression.

On 18th June, the sores having healed, a fresh compress was applied.

June 30th.—"The child having appeared perfectly well during the whole day, exhibited yesterday, towards the afternoon, spasms here and there throughout the body. During the night she got more violent convulsions, which next morning proved fatal. Even half an hour after death cadaveric rigidity had set in. The head was somewhat collapsed, and the fontanels were retracted." The child was twenty weeks old.

I may now be allowed, before passing to the report of the post-mortem examination, to mention an affection in the same child, not indeed very closely connected with the lesion, which gives the case its essential character, but forming a little episode of some interest. I refer to a cephalohematome which was found on the left parietal bone. Even immediately after birth, a small soft part was felt on this side of the head, which excited suspicion of its being an incipient cephalohematome, as the labour had been so easy, the idea of an ordinary swelling from its effects could not be entertained. On the following day, this suspicion became certainty, the collection of blood having increased, and the formation of a bony ring having commenced; the bone forming the fundus was still to be felt. During the following days the tumour increased, but seemed afterwards, on the 14th of February, to have attained its highest development. It was arched, tense, strongly fluctuating, as if it contained a thin fluid. It occupied the inner half of the bone, but so that it was removed about $\frac{1}{3}''$ from any suture. The outer side was indented in the middle, whereby the whole swelling acquired the usual renal form, produced by the parietal tuberosity, as it were, projecting into the tumour. It was $2\frac{1}{4}''$ long, $1\frac{1}{4}''$ broad, almost an inch in height. The tumour was completely bounded by a bony ring, which was weakest at the posterior horn. During the ensuing days the cephalohematome seemed to diminish, and felt as if the fluid had become less thin; but thereupon this peculiarity presented itself, that the swelling for many days again increased greatly, and particularly at the posterior part, where the bony ring had been least developed. Fearing that its contents might by possibility be in danger of being metamorphosed into pus, I made a puncture with a needle into the tumour, but only a drop of red fluid blood appeared. On the 23rd of February the increase of the swelling was arrested, and the bony boundary was everywhere well developed. From this time the cephalohematome began steadily to diminish; it became gradually flatter, and on deep pressure the surface of the bone could be felt, and an active production of flat and knobby bony formations was perceptible, proceeding partly from the edges, partly from the fundus, whereby the tumour was apparently divided into several parts, between which the fluid still circulated freely for a time. It was not until a very late stage that a parchment-like crepitation manifested itself in the upper wall of the tumour; but gradually this disappeared along with the remains of the fluid, and eight weeks after birth the seat of the cephalohematome was marked only by some inequality in the bone, which also at last went off.

To the foregoing report I shall, as the pathology of cephalohematome has in our day been fully investigated and is generally understood, add only a few remarks. It must be considered as settled that this affection arises exclusively in those parts of the surface of the cranium, where the outer lamina of the bone is at birth still undeveloped, and that it occurs by laceration of the minute vessels which in great number connect

the diploë and the pericranium. We, therefore, meet with it only exceptionally and to a limited extent on the frontal and occipital bones, where the outer bony lamina in the mature fœtus is wanting only in small portions (in the case of the frontal bone just over the supra-orbital margin), and therefore we never find it (primarily) on the parietal tuberosity and the adjoining lower half of the parietal bone, where the outer lamina always exists at birth, while, on the contrary, the favourite seat of the tumour is the upper half of the bone, where the same lamina is as constantly absent. In this state of things we must further seek the explanation of the renal form of the tumour mentioned by some authors (Bednar, Rokitansky) which, as will be remembered, was present also in our case: the tumour developes itself in a crescentic form round the parietal tuberosity as around a centre, and only in very rare cases does the limitation occur so late, and is the tension in the extravasated blood so great, that the periosteum is loosened also from the developed parts of the bone, and that the cephalohematome comes to occupy the parietal bone in its integrity. As to the question of treatment, opinions have been divided. While the surgeons (Vidal, Nélaton) advise us to open the swelling with the knife as the quickest and safest plan, the most experienced obstetricians (Bednar, West) leave it to the powers of nature. Our case is in favour of the latter view. Bednar (l. c., p. 376) is certainly right in saying that the cephalohematome, which is covered by an uninjured pericranium, never passes into suppuration.

The post-mortem examination took place ten hours after death.

The body was in good condition, the subcutaneous adipose layer was still very considerable. Length 24 inches from the vertex to the toes. The anterior fontanel was much collapsed, and presented the appearance of a boat-shaped depression with irregular edges 4″ in length, 3″ in breadth; as did the sagittal suture, which had very irregular, strongly curved margins. The measurement of the head yielded the following results: circumference, 17¾″; from ear to ear, 9½″; from the glabella backwards, 10¼″.

The skin was divided with the ordinary curved incision across the vertex, and was reflected backwards and forwards. In the suture the falx cérebri was now distinctly seen to deviate somewhat (1¼‴) to the left of the middle line. Thereupon the dura mater and falx were divided, and the frontal and parietal bones were removed. The meshes of the pia matter were filled with a thin layer of clear fluid, its vessels were present in the usual number, and were of the normal size; the convolutions of the brain were not flattened. The cause of the oblique position of the falx was now found to be a rather greater development of the anterior half of the right cerebral hemisphere, whose inner wall somewhat over-passed the middle line. The hemispheres were without tension, on the contrary, they were flaccid, so that when the head was moved they oscillated from one side to the other. The right hemisphere was opened by a longitudinal cut through the mass, which was half an inch in thickness, and was of the ordinary consistence. A view was thus obtained of an immense cavity, formed by the fusion of the two lateral ventricles and the third ventricle, the foramina of Monro being dilated to an enormous size, the corpus callosum was pressed strongly upwards, the septum lucidum and the fornix had disappeared. On the other hand, through the fluid, at the bottom of the cavity, were seen the corpora striata, (which subsequently on section exhibited the usual appearance) removed from each other by the third ventricle dilated to ¾″ in breadth, in the anterior part of which a round opening of the size of a pea was seen, the largely dilated aditus ad infundibulum, which was lost in a funnel shape inferiorly between the lobes of the pituitary gland. Posteriorly, the third ventricle was prolonged into an oblong, olive-shaped cavity with a very thin superior wall. on which medullary striæ were seen to run longitudinally. This cavity, the enormously dilated aqueduct of Sylvius, was about 5-4ths of an inch, and in the middle, where it was broadest, ¾″; posteriorly, it terminated in a *cul-de-sac* without connection with the fourth ventricle, which was not dilated or morbidly altered. The tubercula quadrigemina were completely absorbed in the upper wall of the cavity, nor was a trace of the pineal gland discoverable.

The posterior horns of the lateral ventricles were comparatively strongly dilated, the wall was here thinner (4‴), the meshes of the pia mater were devoid of fluid, the cerebral mass in close contact with the dura mater and the bone, and its convolutions were somewhat compressed. The inferior surface of the lobes of the cerebrum were attached by fragile filaments of connective tissue to the upper surface of the cerebellum, as the tentorium cerebelli was extremely defective, and represented only by a couple of small lateral portions, terminating posteriorly and anteriorly separately from each other. Through the great dilatation of the posterior part of the lobes of the cerebrum the space assigned to the cerebellum was very limited: the foveæ occipitales inferiores occupied in comparison with the foveæ superiores only a small space, scarcely a fourth of the height of the occipital bone; while the anterior part of the right hemisphere had been more largely dilated than the corresponding left, the reverse was the case posteriorly; here the left posterior cornu was most strongly developed, it extended more deeply downwards and pushed the left half of the cerebellum, which thus acquired a very oblique form, forward. On a level with the spina occipitalis its calibre was contracted, funnel like, to a minute canal, and with simultaneous puckering and attenuation of the surrounding cerebral mass it terminated together with an annexed production of the choroid plexus as a small fibrous bundle in the cerebral membranes, corresponding to the opening in the bone to be presently described.

The ependyma lining, [the dilated cavities was highly thickened and was changed into a white, firm, superficially slightly villous membrane, capable of being with ease peeled off in great pieces, and drawn out between the fingers.

The fluid contained in the brain amounted to from 18 to 20 ounces. It was clear as water and of a saltish taste. Dr. Lehmann examined it chemically in the laboratory of the Municipal Hospital, with the following results:—Its reaction was faintly alkaline; it contained a rather small amount of solid constituents, as its specific gravity was only 1·009, while that of serous fluid in general varies from 1·005 to 1·030. Of the solid constituents the inorganic, and of these again, the chlorides, greatly preponderated; of carbonates, phosphates, and sulphates, the fluid contained only a trace. Of organic constituents, it contained a rather small amount of albuminous matters, both globulin (=fibrinogenous substance), and albumen, moreover, some fat, a little urea, and a trace of sugar.

The bones of the cranium were fully as large as those of an adult, and were well ossified. An active production of new bony mass had been in full progress at the margins, and in the sagittal suture were found several small islands of solid bone. Corresponding to the upper part of the left parietal bone, where the cephalohematome had been situated, a great thickness of the bone was met with, measuring, in some places, two lines. It was produced by the deposition on the outside of the bone of flat osteophytes, which increased in thickness in towards the part which had formed the centre of the tumour, and was here bounded by two very irregular, sharply cut off lines, which at one time, in a curve, approached the middle line, at another, drew back in curves and indentations, leaving a slightly excavated, very irregular part, oblong from before backwards, the only part to which the periosteum adhered somewhat more firmly, and, when separated, carried with it small spiculæ of bone, while it could elsewhere, with the greatest ease, be separated from the surface of the bone. On the inside of the bone, two new osseous formations had taken place, but here rather in the form of irregular juga cerebralia. In the situation of the protuberance of the parietal bone, the bone was very thick, and the surface, as well as in the adjoining part, was externally polished and smooth.

In the occipital bone there was found, in the middle line, immediately over and in the upper part of the spina occipitalis externa, an opening in the bone, of half an inch in length and two lines in breadth, of an oval form, with rounded off angles and edges. The upper extremity of the opening deviated a little to the right, so that it was not situated quite directly in the middle line. In towards the cavity of the cranium the opening was covered with the dura mater, to which the part of the left posterior cerebral lobe, already mentioned, was attached. The surrounding bone was much thickened, and around the opening many nutritive foramina were seen. As a trace of the earlier separation of the bone in the middle line, there was found on the outside, from the opening up to the superior angle of the bone, a slightly excavated line.

The superior longitudinal sinus was seen, an inch over the seat of the spina occipitalis interna, to divide into two sinuses, a greater one to the right, and a somewhat less one to the left, which ran obliquely down over the squama oss. occipitis, to the mastoid process of the temporal bone, and over this to the foramen jugulare.

(To be continued.)

Literature.

NEW EDITIONS.

THOSE who perused Mr. Morant Baker's essay on the "Relations of Life to Other Forces," in the last volume of St. Bartholomew's Hospital Reports, will have formed a favourable opinion of that gentleman's abilities, and be prepared to find his edition of Kirkes's "Handbook of Physiology,"[1] thoroughly up to the mark. The work of Dr. Kirkes was so well and so favourably known, that it is no wonder the publisher should desire to bring out a new edition, revised by a competent person. A text-book, once established, long continues in favour, and for that reason alone, it is desirable that successive editions should be carefully revised. This is especially true of such a science as physiology, and we are glad the duty has been entrusted to one so evidently capable of performing it. The publisher has seconded the editor, by giving good type, good paper, and first-class illustrations on steel and wood. The binding is elegant, but for a text-book we should have preferred it a little more solid, and the edges ought to have been cut. Binders are very negligent on this point, which is of considerable consequence in well-established students' class-books, as these are expected to be well-thumbed. To return to the editor. Mr. Morant Baker wisely considers that it would have been of little use merely to interpolate such new theories and facts as have been recorded since the date of the former edition. Accordingly he set himself to "thoroughly revise the whole work as a handbook for students, and to regard the discussion of all new and crude matter as secondary in importance to a clear enunciation of those grander facts on which, alone, all true knowledge of the science must be founded." A plan like this, naturally involved much more toil than that of merely adding to the original book, notes of contradiction or corroboration, as occasion required; in fact, it necessitated the re-writing of considerable portions—the submergence, so to speak, of the editor in the first author. By it, however, unity of design is secured, the student's attention is not constantly distracted, and a more useful and more readable work is produced. We congratulate Mr. Morant Baker on the manner in which he has accomplished a task of no slight difficulty.

Among the additions to the work, we may notice a brief chapter giving an account of such elementary tissues as had not been previously described, and which will prove very useful to students, as it is very exact and concise. The present writer does not profess to have read the book through, but he has referred to the chapters which relate to the subjects he has lately been occupied with, and has found them eminently satisfactory.

We have been waiting with interest the promised new edition of Professor Galloway's "First Step in Chemistry," and are pleased to announce that it has just appeared, re-written, greatly enlarged and much improved.[2] We remember the first edition of this book, very thin and unpretending, but very practical and easy to understand; introducing students and young people to an accurate knowledge of the *alphabet* of a fascinating science, and leading them on by easy gradations until they could spell out for themselves some of its most important lessons. Then came the second edition, thicker and more complete, then a third still thicker; and now, after being out of print for many months, we welcome the fourth, which has become quite a thick little manual of 470 pages small 8vo., and contains the new nomenclature, besides many other additions—the result of the author's experience in teaching. Whenever we are asked to recommend a book on Chemistry to a beginner, we never fail to mention Galloway's *First Step*, and if this science is to be taught in schools, this is the manual which the pupils should adopt as their guide. We have known rapid progress made by those who have confined themselves to this one book, and no one of average intelligence would follow the author's instructions without laying a broad foundation of knowledge upon which he might go on building with ease and confidence. Professor Galloway's method can scarcely be called new any longer, for it has stood the test of experience, and is thoroughly established in public favour. As arithmetic cannot be taught by lectures alone, but requires the pupil himself to perform the operations of addition, subtraction, multiplication, and division; so Mr. Galloway expects the student to go through a series of exercises as important to a practical acquaintance with chemistry as the four first rules are to those who would comprehend arithmetical calculations. The nomenclature and notation of chemistry, the use of signs and brackets, the construction of formulæ, the mode of expressing chemical changes, the method of determining the quantities of the constituents in given quantities of compounds, and other equally valuable processes, form the subjects of numerous exercises which are so gradually progressive as to advance the student by almost imperceptible degrees from the darkness of total ignorance to familiarity with the great principles of the science. This is the way we learn to read, first the alphabet, then simple syllables, then words of one, two, or three syllables, which we learn to spell for ourselves, and to combine with each other. The method is a thousand times more easy and more effectual than a study of each of the elements with all its combinations in succession, which leaves the last lesson nearly as difficult to acquire as the first. The *First Step* must, therefore, continue to enjoy the favour that was shown to former editions as an excellent plan of teaching chemistry to the young. Medical students would do well to begin with it. Schools that teach chemistry will be sure to give it the preference. Popular classes everywhere will employ it. Students who have no teachers can procure no better work, and the book must have a still wider field; for the number of those interested in chemical processes as manufacturers, is constantly increasing, and we would advise them if they have embarked their money in such things without understanding them, by all means to begin with the *First Step*, and learn what so much concerns them. In any case they would also do well to use all their just influence over those they employ, to encourage them also to the same course.

Having spoken so favourably of the method which we tried years ago, it only remains to specify some of the changes of this edition. First, as we have already said, the new nomenclature and notation is added. This is given at the end of the book. The pupil must first master the old. We quite approve of this, for the old system must be understood, however rapid the progress of the new, as the past literature of the science cannot all at once become a dead letter. Next, the account of electricity and galvanism is re-written, and copious exercises are given. Then the theoretical and experimental exercises are increased all through the work, and selections from the questions of the examining boards have been introduced. The enumeration of these few of the changes is sufficient to show that the new edition will maintain the position acquired by its predecessors.

We may add that there is an index, as well as a table of contents, adding considerably to the usefulness of the book.

A few errata have had to be printed, which the student would do well at once to correct with a pen, as three or four of them are such as may easily puzzle him.

A second edition has been called for of Mr. Henry Smith's "Lettsomian Lectures."[1] In them he treats of such points of the surgery of the rectum as could be compressed into three lectures. Mr. Smith has retained the form of lecture in this edition. At the same time, he has made some additions suggested by his enlarged experience. In the first lecture he dwells upon the close connection of fistula in ano with stricture of the rectum. In the second he treats of stricture, cancer, and polypus; and to this lecture some additions seem to have been made. In the third he enters upon prolapsus and hæmorrhoids, and the use of his improved clamp. There is a great deal of new clinical matter. In the first edition 35 cases were related; now we have 120, and all successful. Mr. Smith says he has now entirely discarded the ligature. This success, together with the fact that this little book consists of the Lettsomian Lectures before the Medical Society of London, delivered by a surgeon of Mr. Smith's well-known character and ability, who has attained the position of president of the society, will, we think, ensure the attention of the Profession to the method propounded of dealing with such universal diseases.

HEALTH OF ST. THOMAS'S.—It is said on good authority that cholera of a severe type made its appearance at the Island of St. Thomas in the last week of December, and that five deaths occurred. Yellow fever still lingers there.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 12, 1868.

QUARTERLY RETURN OF THE REGISTRAR-GENERAL.

As the dark days and thickening fogs of November began to settle down upon us, there were many things which threw a shadow over our feelings, and excited some gloomy forebodings that the condition of our teeming population would be found anything but encouraging at the end of the year. There were disturbances which indicated dissatisfaction, and seemed to show not only mismanagement, but overreaching, disregard of right, and oppression of those who could not help themselves. Besides which there was a deficient harvest, and high prices, just at the time when considerable commercial perplexity was throwing many hands out of work, the consequence of which was a fearful increase of destitution. All these things, and others, led us to anticipate an amount of misery and of suffering which would interfere largely with the welfare of the labouring and dependant classes, and augment the death-rate of the quarter far beyond its usual proportions.

Nothing at such times is more instructive than the periodical returns of the Registrar-General. They correct our misapprehensions, dispel our needless fears, give us encouragement at times when we had lost heart, show us our shortcomings, awaken us to a sense of danger where we suspected none, and with an authoritative voice call us to our duty. It is impossible to overlook them. They have arisen with the progress of society, and may help to solve more problems than those which relate immediately to health and life on the one hand, or disease and death on the other.

Almost the first thing that strikes us in looking over this record is the statement that "the death-rate of the United Kingdom differs little from that prevailing in England and Wales;" so that whatever may have been the difficulties with which we have had to contend, it is fair to infer that they have been equally shared throughout the kingdom; that we in England have felt them as heavily as those in Scotland, or even in Ireland itself. It is satisfactory also to learn that, notwithstanding the distress which has been known to exist in various parts, the death-rate has been much beneath the average. It has been decreasing most plainly for the last three years. In the three months ending with the year 1865, the deaths registered were 121,245, in the same quarter in 1866, they were 117,187, while in the quarter ending December 1st, 1867, they were only 115,863. The number of births over deaths in the quarter, or the natural increase of the population was almost 90,000; but this is reduced by a little more than 30,000 emigrants, so that the increase of the population in the quarter was 60,000.

Though these figures show favourably, and may lead us to think that our condition is not so disastrous as might have been expected, yet there has been, no doubt, less of prosperity and more of privation in the kingdom generally than in previous years. The marriages and births bear testimony to this. The former show a decrease of 2000 in the quarter ending September 30, 1867, compared with the same period in the two preceding years; and the births in the quarter ending 31st December last were 2400 less than the fourth quarter of the previous year. These returns undoubtedly prove that trade must be bad, and the working-classes thrown out of employment, at least to a certain very appreciable extent, and that while these two thousand men cannot find the means of supporting conjugal claims, there must als o be thousands of others exposed to want and woe in no ordinary degree.

But leaving these figures, which are some of the most important, a reference to the notes of the Registrars in some of the different districts will corroborate what we have often remarked as to the value of sanitary improvements, and the danger of disregarding them in every neighbourhood where the human family is collected. The returns inform us of the prevalence of epidemics in towns and villages where measures for the preservation of health are neglected, and reveal the fact on the other hand, that by due and persistent care they may be almost, if not wholly, avoided. It is high time that men should be taught to take care of themselves. They have not fully learnt the lesson yet. Some allowance must be made for unavoidable ignorance, and in some cases for inbred want of observation; but we hope before long that the better taught, and influential portion of the community, will feel the importance of the subject, and soon in every locality all will become fully aware of those contaminating influences which inevitably engender and foster disease, and feel no security until they have removed them.

"CROWNERS' 'QUESTS."

AT a moment when the dignity of the ancient court of the Coroner is said to be endangered by the encroachment of the Government, and when more than one of these officials are resenting the refusal of the Home Secretary to produce prisoners before them, there has occurred a case which shows how justice may be set at defiance by a Coroner's Jury.

On the 15th of January, a woman went to the Metropolitan Dispensary, and said her husband had burst a bloodvessel. The boy rang for the Resident Medical Officer, who is, to our knowledge, one of the most diligent, kind, and active officers in London. Before he could get down stairs, the woman had gone away, and *had not left her address.* She had told the boy the doctor had been with her husband that day, but as he had finished all the visiting for the Dispensary, this information did not enable him to decide on the case where he was wanted. The man's house was very near, so that but for the poor woman's excitement and hurry, the patient would have been visited in a few minutes. An inquest was held (as the man died) at St. Bartholomew's Hospital, and the sage jury, presided over by the dread Coroner, without calling

upon the medical man in question for any explanation, proceeded, *in his absence*, to append a censure to their verdict for his neglect in not responding to the summons that had been made. Now here, we say, is an injustice upon the face of it. To condemn a man for neglect without his having the opportunity of speaking a syllable in his own defence, is a disgrace to the jury that so hastily jumped at an incorrect conclusion, and to the Coroner who presided over the inquiry. If every man's character is to be thus assailed, who will be safe? Here is a moral "stab in the dark" that might suffice to ruin many a worthy young surgeon, and which none but those of the very highest character could suffer without serious injury.

We happen to know much of the working of the Metropolitan Dispensary. It is one of the best charities of the kind. The Resident Medical Officer, Dr. SOUTHWOOD, is of an age and standing, that such a decided blunder cannot do him the harm it would a younger man. His diplomas date from 1834. Seven or eight years ago he graduated at the University of St. Andrews. Before then he was a Fellow of the Royal College of Surgeons. He has been for many years attached to the Dispensary, and enjoys the confidence of the whole district, as well as of all his professional brethren with whom he has been brought into contact. He brings to the discharge of his arduous duties unusual qualifications, skill, and experience, far superior to that which can be expected in all such positions, and a rare kindness of manner and sympathy with the sick poor, which must ever make him valued as their best friend, whenever his services are needed.

We are, therefore, by no means surprised that the Committee of the Dispensary, "after having fully and carefully investigated the circumstances," should have come to the conclusion that "no blame whatever is justly attributed" to Dr. SOUTHWOOD, and that they have expressed a decided opinion on the impropriety of such a censure having been "passed, without giving Dr. SOUTHWOOD an opportunity of being present to render any explanation in his power."

We, too, feel strongly that a gross injustice has been perpetrated, and we are sure that every one of Dr. SOUTHWOOD'S professional brethren will continue to feel as much confidence in him as the Committee of his Dispensary. We, therefore, tender him our best sympathy under the annoying imputation, and protest against the wrong that has been inflicted by the carelessness or haste of the jury.

Notes on Current Topics.

The British Lying-in Hospital, and the Female Medical College.

THE statement which we laid before our readers last week as to the circumstances attending the adoption by the directors to this institution of a resolution calling for the resignation of Dr. Eastlake, their physician, has elicited the following communication from Dr. Edmunds, which, being addressed to the editor of THE MEDICAL PRESS AND CIRCULAR, and not marked "private," we feel ourselves justified in publishing:—

"London, February 7, 1868.

"SIR,—Many friends have called my attention to the shameful and injurious article in THE MEDICAL PRESS AND CIRCULAR of the 5th inst.

"In that article, you adopt, endorse, and republish statements which I can only describe as impudent falsehoods, while your comments and editorial warning are obviously intended to injure myself and other well-known professional men, who are the administrators of the College.

"A suitable retraction must be inserted in your next number, or I shall be under the necessity of vindicating myself before a jury.

"I am at home every day until one o'clock, and shall be willing to signify my approval and acceptance of the proposed article in proof.—Your obedient servant,

"JAMES EDMUNDS, M.D.,
"Hon. Secretary to the Society."

Dr. Edmunds, or any other gentleman who may consider that our observations apply to him, can only call on us for a retraction, either on evidence that our facts are inaccurate, or our comments on them uncalled for.

We have in the communication of Dr. Edmunds, no information whatever on the subject, but after a careful perusal of the lengthened defence addressed by Dr. Edmunds to a medical contemporary, we are constrained to say that it offers little information relevant to the question, and none that substantially affects the accuracy of Dr. Eastlake's statements. It enters largely into a variety of accusations against Dr. Eastlake, and into the *modus operandi* of the removal of the acting medical officers from the direction of the hospital, but it does not attempt a denial of the fact that instruments were applied by the midwives without Dr. Eastlake's knowledge (and, as that gentleman says, contrary to his repeated orders, and to the great injury of the patient), and that the directors by visiting such an infraction of discipline with a mild rebuke and expelling Dr. Eastlake, *practically* gave their countenance to the offence, and dismissed the complaint.

After a careful perusal of the notice of which Dr. Edmunds complains, we cannot find that any commentary on the letter of Dr. Eastlake has been made which is not called for by the allegations put forward in that communication. We shall be glad to afford Dr. Edmunds every opportunity of contravening the statements, and should he favour the Profession with a convincing vindication of the Directors of the British Lying-in Hospital, to withdraw any observation which may appear to be unjust to them. We must, however, decline, until further information is before us, to modify our opinions, or to submit our editorial observations to the correction of Dr. Edmunds, and, while we desire to express our readiness to modify or retract any statement which we may find to be incorrect, it would be premature, with the uncontradicted allegations of Dr. Eastlake's published letter before us, to repudiate any of his statements.

Public Health.

WE select from the weekly return of the Registrar-General the following particulars:—There were 4712 births, and 3182 deaths registered in London, and 13 other large towns of the United Kingdom, during the week that ended on the first of February. The annual rate of mortality was 26 per 1000 persons living. The births of 2364 children were registered during the week in London, 1207 being boys, and 1157 girls; the average number for the corresponding weeks of the previous ten years is 2288. The deaths registered in London in the week were 1394, being 235 less than the estimated number for that week.

There were 286 deaths from zymotic diseases, 24 from small-pox, 26 from measles, 31 from scarlatina, 11 from diphtheria, 65 from whooping-cough, 47 from fever, and 15 from diarrhœa. There were registered also 170 deaths from phthisis, 183 from bronchitis, 80 from pneumonia,

and 43 from diseases of the heart. From burns or scalds there were 10 deaths recorded—viz., 7 children and 3 adults. Five infants died from suffocation, and 2 persons from privation, while 2 were killed by horses or vehicles in the streets. One death resulted from "chorea, occasioned by fright," at the Clerkenwell explosion.

In the different towns the annual rate of mortality last week was as follows:—In London, 23 per 1000; in Edinburgh, 27; in Dublin, 34; in Bristol, 28; in Birmingham, 24; in Liverpool, 31; in Manchester, 29; in Salford, 33; in Sheffield, 25; in Bradford, 24; in Leeds, 24; in Hull, 24; in Newcastle-upon-Tyne, 25; and in Glasgow, 32.

The Fever at Terling.

"No amount of hunting up of private nuisances will avail without the scavenger." So says the clerk to the guardians. He also reports that the Privy Council informed him in answer to an inquiry, that his guardians "had no power by law to scavenge," but that they "could only follow up a private nuisance." Acting on this advice, the guardians "dropped the cart" they had employed during the epidemic of cholera in 1866. This statement, we consider, calls for an explanation. If the guardians really had no authority at all, and were so advised by the Privy Council, it is absurd for public opinion to hold them responsible for the abominations pointed out in Dr. Thorne's report. Again, if such is the state of the law after all our efforts to improve our sanitary legislation the sooner Parliament recommences this kind of work the better.

Reformatories.

For more than a year compulsory detention, with hospital accommodation, and some opportunities for fallen women to return to a virtuous life, have been tried at Portsmouth, Chatham, and Aldershot. Differences of opinion seem to prevail as to the good that has been effected, but it should be remembered so utterly wretched are many who ply their disease-spreading trade amongst our soldiers, and in our large cities, that the mere erection of a lock hospital attracts many of them to its neighbourhood. This one fact will silence many who objected to compel these women to submit to examination and treatment. It effectually disposes of the fear that they would do all they could to avoid it. Another encouraging fact is that the conduct of the women is reported by some to be less flagrant than before the act was in force. Nor is this all; for we are informed that at Chatham alone thirty-nine have within ten months been restored to their friends or entered reformatories. A goodly number will also be returned from the other towns as having abandoned their mode of life. Now, every reformed prostitute is a clear gain to the community, and therefore we think this part of the question should not be omitted from any debate as to the extension of the act. Facts like these cannot be too frequently repeated, since the number of good and charitable people who are hostile to compulsion of this kind is very large. Nor should we omit to say that the reformatories are too few, and that those which exist are not sufficiently supported. In one a wing is planned, and the building of it is only delayed for want of money; while in another, only six were admitted on a late occasion out of twenty-eight applicants. The twenty-two refused had no hope of escaping from the life of shame and woe they were willing to quit, and so were thrown back upon the streets. This is surely a blot on our boasted christianity, an opening for our charity, a fact to make Englishmen blush. The wail of these prodigals returning to society by these half-open back doors, and thrust back to vice for want of funds, should excite the commiseration of those whose victims they have been. Let it not be repeated again and again that there is not room for the outcasts in our reformatories, nor that there is not money enough to carry on these institutions. Thousands are being squandered in less urgent cases. New charitable plans are constantly being formed. When a great scarcity occurs like that at the East-End of London, there are even rival agencies ready to contend for the ground. We trust, then, that reformatories will not be forgotten, but will be so well supported that they may be able to carry on their work efficiently.

isappeared.

One of the most perplexing problems that can vex a civilized community has lately occupied attention. The Rev. B. Speke, brother of the well-known African traveller, who came to so untimely an end, disappeared on the 8th of January, and no clue has been found as to what has become of him. He reached London by train that evening, called at the house of his brother-in-law, left his luggage there, went out and bought a new hat, ordering it to be sent before seven P.M., and from that time left no trace. He had come to town for the purpose of being at the wedding of an intimate friend the next morning, and had appointed to see another person at his brother-in-law's in the evening. That person came and waited for him an hour; then went away, leaving his address, but Mr. Speke never returned. Many conjectures have been made, but as the lost man was one of character, and is described as of "well-balanced mind," and, as his circumstances were not likely to lead to his intentionally quitting his usual sphere, the dark suspicion that he has met with foul play grows with the time that elapses since his mysterious disappearance. There is something grimly sensational in the idea that a sane and healthy man can thus be decoyed or forced away, and that the crowded streets of the modern Babylon should be as unsafe as a desert. True, the hat he wore has been found, but that affords no assistance, for it was picked up a few hours after in a thronged thoroughfare, and might have been purposely placed there to divert attention. Terrible suspicions cannot be warded off by plausible explanations. Moreover, they are strongly supported by other facts brought to light. For instance, a gentleman of undoubted respectability has related how some one, evidently acquainted with his pursuits, and pretending to be a detective, tried to induce him to enter a cab in order to drive to Bow-street, to give evidence before the magistrate in a case that might well concern him. He would not go because he had another engagement, but agreed to drive there in an hour. The false detective urged compliance very strongly, but in vain; though the gentleman would certainly have gone but for the fact that his engagement was pressing. But for this, we might have had to speak of two mysterious disappearances. Another ugly fact is that the friends of Mr. Speke have been shown a considerable number of unclaimed bodies. How have all these passed away from their usual resorts without being missed? It is, we are aware, no uncommon thing for people voluntarily to leave their homes in a strange unaccountable manner, and they are often next heard of in a distant country. But for a clergyman of a country parish to visit town, make appointments for nearly every hour during his stay, and

for his horse to be at the station to meet him on his return by a fixed train, and then in the middle of those appointments to disappear in a manner so secret as to baffle every attempt to trace him, is unprecedented. Of all the explanations that can be imagined, those are the most natural which suggest that a dark crime has been committed. Unlikely as it may be that a struggle for life took place where the hat was found, we cannot divest ourselves of the idea that this gentleman might have been decoyed into some more lonely park, perhaps on a mere pretence of charity, and robbed, and then on resistance, murdered. We would fain hope not, but the facts seem to point to this. And what a state of insecurity does this reveal in the centre of the most populous city! Every one, at any rate, ought to take warning how he trusts himself to the representations of a stranger. That incident of the pretended detective opens to view a host of dangers for cautious Londoners, much more for casual and inexperienced visitors to the metropolis.

Getting Money.

For years past this has been one of the peculiar characteristics of this country, and now, perhaps, more than ever, we may be fairly considered as a money-getting community. Our commerce was never more widely extended than it is at the present day. Men are embarking their capital in mercantile transactions to an unknown extent, and devoting their energies and their skill night and day, without intermission, to the particular mode of industry which they have chosen. These things necessarily have a mutual bearing from the interchange they create, which is, in fact, the essence of all mercantile transactions. No man can exert himself in this way without conferring a benefit on others, and hence the effect which all commerce has in advancing general civilization, and contributing to the welfare of the species in various ways, as well as creating a good feeling between both men and nations. But while all trade has a general bearing, there is no doubt that the individual motive for engaging in it is mainly the idea of profit; in other words, making money.

We have been led to these remarks by a pamphlet[1] which has fallen in our way from the pen of Dr. Gairdner, the eminent professor in the University of Glasgow, who looks at the subject from a moral point of view. He takes us back to Greece and Rome, and gives us the ideas of their philosophers and poets as to money-making. He then examines the question in reference to the condition of society in the present day, and discusses at considerable length the true principles on which all business transactions should be conducted. It would take us too far to follow him through his whole course; but there is one point we cannot overlook, and that is professional remuneration, and chiefly in regard to ourselves. He refers to Jenner, whose "example," he says, "is in accordance with a principle now firmly established in the Medical Profession, that the *status* of its members is considered to be lowered by any attempt to establish a *property* in any remedy, or other invention for the relief of disease, whether by concealment or by patenting, or otherwise advertising the invention for the benefit of its presumed owner." This is a principle which, on the whole, for the honour of the Profession, we would ever uphold. That day would be an evil one for its members in which they should descend from the high and reputable position which they now occupy to employ mean and unworthy methods of increasing their income. At the same time, we cannot shut our eyes to the fact that commerce is the high road to wealth, and that the members of an honourable profession, whose services are often more valuable than gold itself, are compelled to rest content in the usual way with the most modest remuneration.

1. On Certain Moral Aspects of Money-getting. By W. T. Gairdner, MD., Professor of Practice of Medicine in the University of Glasgow.

Venereal Diseases in the Navy.

The statistical abstract of the health of the navy furnishes a most satisfactory report of the result of the operation of the Contagious Diseases' Act in the three years in which it has been in operation. In that interval, the number of cases of syphilis treated in one quarter of the year in the Naval Hospital and Marine Infirmary, has declined from 71·6 per 1000 of the mean force first to 58, and at last to 26·3 in the last midsummer quarter. If this reduced rate be established, the effect of legislation in this great evil is a subject for marked congratulation and a triumphant vindication of the system of supervision. It is, of course, to be borne in mind that, in the case of the army and navy, the system may be applied under circumstances much more favourable than amongst the civil population—nevertheless, the three years' experience of the inspecting arrangements prove, beyond a doubt, that there is no difficulty in carrying the Act into effect; and that, when properly administered, their operation is attended with the most valuable results. Already objects have been attained of incalculable advantage to both services, and still greater gain in a social and moral point of view.

Winter Resorts.

The *London Scotsman* claims for the northern countries, and more especially for Edinburgh, a very much more genial climate relatively to that of the South of England than Scotland usually receives credit for. "The readings of the thermometer for the last three months show an average temperature for Leith for that period exceeding that of London by no less than four and a-half degrees. So that taking Edinburgh at about half a degree colder than Leith, there still remains a difference of four degrees in its favour as compared with London. The medical men of Edinburgh are now becoming alive to this fact, and generally keep their consumptive patients in town till near the end of January instead of sending them south, as used to be the practice, by the beginning of November. During the latter part of winter, and during the whole of spring, however, the temperature in the north is lower than in London, though not by so much as is usually supposed, but in the summer the heat in London is far greater than in Edinburgh. In fact, as might be expected from its position, the climate of the metropolis is more subject to extremes of temperature."

The Vacant Coronership.

The legal candidate, probably influenced by the division of the medical interest, has renewed his application. This should urge the medical men who have any influence in the matter to take active measures in support of the best qualified medical candidate.

New Books.

The last month has produced a few new books worthy of note, and many new editions of works already known to the profession. Dr. J. Matthews Duncan has issued, through the firm of Edmonston & Douglas, at the price of

18s., an octavo book of over 500 pages, entitled "Researches in Obstetrics." Dr. W. J. Little is the author of a 140 page volume, "On Spinal Weakness and Spinal Curvatures," which is brought out at 5s., by Longmans & Co. "A Synopsis of the Pathological Series in the Oxford Museum, for the use of Students, and on the plan of the Hunterian Catalogue," is issued by Macmillan; and Dr. J. I. Mackenzie is the author of a shilling pamphlet on the "Climate of Sidmouth." We receive from America two new books—Dr. Antoine Ruppaner "On Laryngoscopy," an octavo, of 160 pages, with illustrations, at 9s.; and Dr. Philip S. Wales, of Philadelphia, "On Mechanical Therapeutics," a treatise on surgical appliances, bandaging, minor surgery, orthopraxy, and the treatment of fractures and dislocations, a large illustrated work, at the price of 28s.

The file of new editions is led by Mr. Macnamara's handsome 7th edition of "Neligan's Medicines," published by Fannin & Co., at 18s.; followed by the second edition of Mr. Henry Smith's "Surgery of the Rectum;" the 11th of Dr. Southwood's "Philosophy of Health;" Mr Baker Brown on "Ovarian Dropsy;" Mr. Gamgee's "Veterinarians Vade Mecum;" and, lastly, the 8th appearance of Dr. Dewar's remarkable pamphlet on "Sulphurous Acid Gas," the new panacea for all diseases.

The Carmichael Prize Essays.

The Royal College of Surgeons in Ireland advertised more than twelve months since for essays in competition for the prize of £200 for the best essay, and £100 for the second best, on "The Medical Profession and Education," endowed by the late Mr. Carmichael. For the competition, five essays have been sent in, and three judges have been appointed by the Council to peruse them, and award the prize, if they shall find sufficient merit in any. Should the arbitrators decide on awarding the prize to any of the essayists, it will be conferred on the successful competitors in May next.

At a meeting held in the Music Hall of Edinburgh, respecting the representation of Scotland, Mr. Duncan M'Laren, M.P., has been exhibiting great hostility to the St. Andrews medical graduates with unpardonable ignorance of the whole question involved in their claim to be admitted to the franchise. We commend his remarks to the St. Andrews Association, and recommend that body to take active measures to neutralize his speech, and to oppose his return at the next election.

The Lettsomian lectures this year are on "Pneumonia and Pleurisy in Children." They are being delivered by Dr. Buchanan. The third and last lecture of the series is on Monday evening the 17th inst.

A pamphlet on "Street Tramways for London," by Charles Mackay, L.L.D., the author of "Life and Liberty in America," has lately appeared, and very properly condemns the vehicles in which Londoners consent to be transported from place to place. We wish the scheme for street tramways every success.

Sir Charles Selwyn, M.P. for the University of Cambridge, has been appointed Lord Justice of the Court of Appeal in Chancery, so that there will shortly be an election for the University.

There is a vacancy in the coronership for the University of Oxford.

The pupils of Mr. Tatum, whose retirement from St. George's Hospital we lately announced, have opened a fund for presenting him with a testimonial. Mr. Tatum has been connected with St. George's for upwards of forty years.

Dr. Wood, it is said, will not contest the seat for the London University, but retire in favour of Mr. Lowe. Dr. Wood is an LL.D. of the University, and a staunch friend of the medical graduates.

An East London Children's Hospital has been opened in the Limehouse district. Mr. Heckford is the resident medical man.

Dr. Chowne, on his retirement from the office of physician, which he has held so many years, has been appointed Consulting Physician to Charing-cross Hospital. Dr. Silver is a candidate for the vacant Assistant-Physiciancy.

We understand that the Municipal Council of Dublin has intimated to the governors of those hospitals which are in receipt of a grant from the city, that it is considered advisable that the Corporation should be represented on the directory of these institutions. Certain of the hospitals have responded to this suggestion by the election of three members of the Town Council into their administrative committees, and it is probable that the request will be universally acceded to.

We learn with much regret of the very alarming illness of Mr. Ledwich, the esteemed chief of the Ledwich School of Medicine in Dublin, and Surgeon to Mercer's Hospital. The illness under which Mr. Ledwich suffers is rheumatic gout in an aggravated form, and of a retrocedent character. Our inquiries, as we go to press, inform us that the attack remains unmitigated, but not aggravated within the last few days.

THE PAST MONTH.

Those who watch our weekly abstracts of the bills of mortality will have noticed that January, 1868, has been an unusually healthy month. Altogether nearly 800 deaths less than usual were recorded. In the very coldest part of the month it was observable that the mortality fell considerably, so that the relations between weather and disease are not yet fully appreciated by those who look upon severity as a necessary calamity. The weather was not only unusually severe, but very unsettled and changeable; it was a month of violent atmospheric disturbances as well as keen frosts, and excessive fall of rain.

We extract from Mr. Allnatt's interesting summary the following particulars of the meteorology of the month:—

"Cloud.—From the 1st to the 7th, during a succession of bitter frosts, the sky was completely covered by an impervious canopy of cloud. On the latter date the sun shone throughout the day. From the 8th to the end of the month the prevailing modification was the cirro-cumulo-stratus nimbus, or true rain-cloud.

"Wind.—Dreadful tempests, characteristic of circular storms, committed wide-spread destruction on sea and land throughout England and portions of Continental Europe; they were generally equatorial, and ranged from S. to S.S.W. and S.W.

"Thermometer.—From the 1st to the 7th the day temperature ranged from 24·0 deg. to 29·5 deg., showing a variation of 5·5 deg., and an average of 26·7 deg., which is upwards of 7 deg. below the mean. The range of Fahrenheit's thermometer was from 5 to 12 deg. below the freezing point. In the second week, from the 8th to the 14th, the temperature was subject to greater oscillations. The mean was from 28 to 44·2 deg., a difference of 16·2 deg. From the 16th to the 31s

the nightly range was from 29 to 47 deg., a difference of 18 deg., and the range of mean daily temperature, deduced from two diurnal observations, from 47·7 to 31·2 deg., giving a total range of 16·5 deg. Frosts occurred nightly up to the 12th, and again on the 20th and 21st.

"Barometer.—The range of the barometer (600ft. above the sea-level) was from 28·70 to 30·00 inches, making the ultimate variation 1·30in. The *minimum* registration was during and on the two days preceding the gale and heavy rainfall of the 22nd, when the oscillations were as follows:—On the 20th, 28·70in.; 21st, 29·40in.; 22nd, 28·70in.; 23rd, 29·35in.; and on the 24th, 29·90in.

"Snow and rainfall.—The mean depth of snow deposited on level ground in tranquil spots was about four inches, two inches from a fall on the 1st, which lay till the 5th, when sleet and rain occurred, the surface became partially thawed, and a pellicle of ice formed. On the 6th two inches more fell, and the superficies again became frozen. On the 8th, the same process was renewed, so that there were in undisturbed places three impervious layers of ice-bound snow.

"On the 12th, at 8 p.m., the wind having become almost due S., the thermometer, which had sunk to 28 deg., rose to 32 deg., and a thaw set in. At 9 p.m., the accumulated solid ice fell from the branches of the high trees with successive crashes of considerable violence. On the evening of the following day the snow had almost entirely disappeared.

"Great floods are reported from various parts of England and destruction of property; the aggregate amount of united snow and rainfalls was upwards of 2·50in. above the mean. The tempest on the 16th was attended by lightning and thunder, and torrents of rain fell into the sea near Eastbourne.

"Barring the minor frosts there were during the past three months, thirty-one nights on which the temperature fell several degrees below Fahrenheit's point of congelation. In November there were three, in December sixteen, and in January twelve."

Society Proceedings.

SURGICAL SOCIETY OF IRELAND.

Dr. ADAMS, President of the College, in the Chair.

(Continued from page 123.)

MR. R. MCDONNELL read the following paper:—

CARIES.

Mr. PRESIDENT AND GENTLEMEN,—I wish to bring under the notice of the Society some cases which I conceive are well calculated to elicit some discussion on an eminently practical question—viz., How far the method of treatment by caustic advocated by Dr. Kirkpatrick is applicable to diseases of bone, especially diseases of bone in the vicinity of joints?

When novel, I may almost say, startling, propositions of this kind come before a body of practical surgeons, such as I see around me, some of them at once recommend themselves to us for trial; we say at once, that sounds like a good proposal; we almost wonder sometimes that it has not been thought of sooner, and, if I may use the expression, our surgical sense tells us that we are justified in putting the new operation or method of treatment to the test of experience; yet, when weighed in this balance, it may be found wanting.

On the other hand, some of these novel proposals which do not at first recommend themselves to us, which do not sound to us like good sense and good surgery, have been found by experience to be real acquisitions to the science and art of surgery.

If we were now considering, for the first time, the proposal of amputating at the ankle-joint after Mr. Syme's method, I doubt if this operation, which we now admit to be oftentimes so good in practice, would, when as yet untried, stand much in favour.

I feel tolerably certain that the treatment of stricture of the urethra by the immediate plan if, in ignorance of its practical results, it was now under debate, on theoretic grounds it would be condemned. Yet, experience has established it as good practice.

While I admit, therefore, that surgeons must generally look to results, and that the progress of surgery must ever be eminently tentative, yet that is no sufficient reason why every wild project is to be put to the test of experiment.

I should be sorry to be understood to apply the term wild project to Dr. Kirkpatrick's proposal for the treatment of bone affections, yet I may be permitted to say that, in my judgment, it is not one of those propositions which, as I have said, recommends itself to us at first sight. It must fight its way up hill before it can obtain general adoption. It must fight its way not, I conceive, so much against prejudice as against a well-grounded caution.

As the plan is by no means free from pain, as it is applicable to disease most liable to occur in frail, irritable subjects, and one which, under any treatment, has a tendency but too often to go on from bad to worse, medical practitioners will be naturally timid about having recourse to a method of treatment which causes suffering, and which may be blamed for what is in reality only due to the natural tendency of the complaint itself.

Yet I am quite satisfied that, at the hands of the members of this Society, Dr. Kirkpatrick will meet with praiseworthy promptness in impartially considering the merits of his proposal, a candour in renouncing prejudices, in short an anxious desire to give their approval to the plan should it prove fairly deserving of approbation.

The following are the cases which I wish to bring under the notice of the society:—

Case 1.—Denis Blayney, aged 21 years, was admitted to Dr. Steevens' Hospital on June 8th, 1867, suffering from disease of the left knee-joint. The patient was a member of a phthisical family, and from childhood had suffered from occasional pain and weakness in the affected joint. Twelve months before admission when leaping out of a cart he had strained the knee; for a time after this injury he suffered acute pain in the joint, but this gradually subsided, so that he could walk with a stick.

On admission the joint was swelled, an abscess had formed and burst near the head of the fibula; the patient could flex and extend the knee to a considerable extent without pain. When the patella was pressed upon it was found not to be floating, it did not strike against the femur. At this time the patient could walk with a stick; he suffered more from a feeling of painful fatigue in the joint than from absolute pain. His rest was not broken by startings of the limb at night.

His treatment consisted of nourishing diet, cod-liver oil, syrup of the iodide of iron, and a neatly adjusted fixed apparatus, which kept the entire limb in a state of absolute rest.

In spite of every precaution a large abscess formed above the knee; the patient's general health suffered, and his rest was broken by painful startings; amputation was performed on September 14th; the patient made a good recovery. He was able to leave his bed in three weeks, and was dismissed from hospital on November 14th, 1867.

It is the condition of the knee-joint that I wish to direct particular attention.

Dr. McDonnell proceeded to say that in this case acupressure was used, and there was an interesting fact connected with it which he might mention. The flap operation was performed, and Mr. William Stokes, who was present, kindly assisted, and with great dexterity applied the needles on the vessel. Forty-eight hours afterwards these needles were withdrawn, and as no hæmorrhage came from the smaller vessels, they thought they would remove that which compressed the femoral artery also. When the needle was withdrawn, a spurt of blood came right across the bed three times with such force as not to leave the slightest doubt that it was from the femoral artery it came. He (Dr. McDonnell) immediately pressed on the groin, and kept up the pressure for fifteen minutes, until a spring compressor was brought. When he withdrew his fingers for a moment to allow the compressor to be applied, there was no return of the bleeding. Afterwards, in the evening, he removed the compressor, and there was no return of bleeding, but he was so apprehensive on the subject that he reapplied the compressor, and one of the pupils remained by the bedside of the patient all night. Dr. McDonnell then exhibited a drawing showing the condition of the knee-joint. The comparative state of health of the right side, as compared with the left side of the joint, was remarkable. The cartilage remained, and was healthy, while on the other side it was entirely gone. The portion of the femur was denuded of cartilage, and the inside of the patella also. Now, although the cartilage was gone, the patient repeatedly, and even the day before the operation, pressed his patella down, and said it did not give him any pain. Dr. McDonnell then showed the bones: On the right side the cartilage was to be seen quite healthy, and when he made a section, and threw it

back, it was found to be as thick as ever, and not eroded in the place near the bone. They could see the diseased bone, and also the back of the femur; where the periosteum was thickened and thrown back there was to be seen very extensive disease of the bone. On the tibial side there was healthy cartilage, on the other side the cartilage was entirely gone, and a series of sections were made, showing the condition of the bone filled with what might be called tuberculous matter. It became smaller as it went down, so that there they had the apex of a cone. The patella was entirely denuded of cartilage. In the head of the tibia it was cancellated disease, and not to so great an extent as that of the femur, although the disease was existing in both bones.

Case 2.—Henry Grady, aged 58 years, was admitted to Dr. Steevens' Hospital on July 10th, 1867, suffering from disease of the left ankle-joint and bones of the foot. It is needless to give a detailed account of the case; it was one of destruction of the ankle-joint, and complete disorganisation of the surrounding structures from the so-called strumous disease, commencing five years before.

On admission the patient was in a wretchedly debilitated state ; by tonic treatment he improved so far that on August 17th he was deemed in a fit state for operation, and the limb was amputated below the knee. He made a good recovery, and left hospital on October 23rd.

We have before us the diseased parts.

Dr. McDonnell then exhibited the diseased specimens. He had made a section right through the middle, and they now had one-half of the tibia macerated, and showing, in a very beautiful way, a throwing out of new bone, and also the diseased structure like melted sugar. In the other portion the cartilage was entirely gone, but the ends of the bone were not occupied by granulation as in the other case. The bone was bare, the disease was not limited to the end of the tibia and the astragalus, but all the bone was diseased, and was as soft and as easily cut as a piece of cheese. The whole of this structure had undergone that kind of fatty degeneration which was found in those affections called strumous, or scrofulous disease. He did not think that a good term, for although it occurred in strumous subjects, they did not find it to contain those deposits under the microscope, which were found in tubercle of the lung.

Case 3.—Mary Anne Champ, aged 26 years, was admitted to Dr. Steevens' Hospital on September 6th, 1868, suffering from an affection of the left foot. She stated that some six months before she had given the foot a twist, and that since then it never had been comfortable; she was easily tired on it, and in walking could not spring on it. The arch of the foot was puffed, and there was a distinct swelling over the cuboid bone. A small abscess came forward at this point and broke. After this she left hospital on October 28th.

By an accident, however, the diseased foot got another twist, and this seems to have given an impulse to the disease. Abscesses formed on the dorsum and sole of the foot. The patient's rest was broken with distracting pain only relieved by large opiates. and on December 14th she returned to hospital to seek relief by amputation.

I performed Syme's amputation at the ankle on December 14th.

The patient has since gone on remarkably well, and is now convalescent.

Dr. McDonnell said that in this case he had also used acupressure, and nothing could have been more satisfactory. The needles were withdrawn without the slightest hæmorrhage at the end of 48 hours. These were the cases he had to bring before the Society. He had no opinion to give. He held no view as yet on the subject of treatment by caustic. He considered it an open question, but before adopting it as a practice, he thought they were bound to look carefully into the pathology of cases like these, and ask themselves the question whether, considering these things seriously, they could reasonably expect good results from the treatment by caustic in cases of this kind? In the last case the cartilage was nearly gone, eroded between the metatarsal bone of the great toe and the internal cuneiform. In the next articulation the cartilage was gone also, and in the third the joint was healthy. In these three specimens they had an excellent illustration of this kind of bone disease extending to the joints, and they were bound to study very closely the pathological conditions before they adopted the mode of treatment proposed by Dr. Kirkpatrick. In the first and second case the disease had undoubtedly made very extensive progress. The third case might be one in which Dr. Kirkpatrick would have thought his treatment more suitable ; but he (Dr. McDonnell) did not think it was likely to have done much good. Having seen the appearances which the bone presented, he did not now regret the course he had adopted. He might say that Dr. Kirkpatrick saw two of the cases, and spoke of them as cases to which he thought his mode of treatment might have been applicable, but he did not know whether, if, under his own care, he might not think them too much advanced for it.

Dr. KIRKPATRICK said, although he professed himself most strongly in favour of the treatment of diseases of the bones and joints by means of caustic, he had not put it forward as capable of effecting a renovation in cases such as the first and second specimens exhibited to the society by Dr. McDonnell, where total disorganization of all structure had taken place. His treatment was specially proposed for arresting disease at its outset in the cancellous structure. He also recommended it in more advanced cases, but where disease was still limited in extent so that an incision being made the caustic can be brought into contact with the carious bone. But in the paper which he read before the British Medical Association, he advised against interference where the remedy could not be brought into contact with all the diseased structure. With the permission of the Society, he would read the extract he alluded to :—

"Although strongly recommending this treatment for the early stages of acute articular osteitis, and also for the very advanced periods when caries is established, or when a whole joint is converted into a foul suppurating cavity, my experience does not warrant me in advising the practice so strongly in the intermediate periods, where the head of a bone may be the seat of a diffused suppuration, possibly communicating with the joint itself. The caustic, I fear, in this condition of parts could not extend sufficiently to protect from the constitutional disturbance and risk of pyæmia that might follow.

"In fact, the remedy cannot be brought into perfect contact with all the diseased structure, and thus the caustic tunnel, which is safe and effectual, acting as a drain and relieving tension when employed in the case of simple articular osteitis is an unsafe remedy when introduced into the cancellous structure of a bone, when purulent softening is only commencing, at it may produce irritation, and be followed by abscess and constitutional disturbance."

In Dr. McDonnell's third case, he thought the caustic treatment might have been fairly tried. He had further to remark that during the last six years that he had been engaged in following up this treatment, he had read in the London journals several cases when, after excision or amputation, disease of very limited extent was discovered, which, in his mind, would have been easily reached and removed by the caustic application. This treatment which he had brought forward was not a mere matter of theory, for he had always several such cases under care at the North Union, which he should be happy to exhibit to any member of the Society who might honour him with a visit.

Professor HARGRAVE said the drawing exhibited by Dr. McDonnell appeared to him to be a representation of the state of the knee-joint as described by Sir Benjamin Brodie, when the disease commenced in the synovial membrane, and extended to the bone. There was a point in connection with disease of the knee-joint to which he thought they were not sufficiently attentive. They were too much inclined to say the patient suffered from disease of the cartilage, and too often overlooked a more serious disease—namely, where the disease occurred in the cancellated structure. The disease more frequently commenced in that structure, it gave intense pain, and extended to the knee-joint, implicating the cartilages and other structures. He was satisfied that a cure might be effected in many cases with sufficient pains, time, and rest. The work lately published by Mr. Hilton on rest in pain was most valuable ; and his own experience in the hospital with which he was connected fully confirmed all that Mr. Hilton had so well said on that subject. If they carried out that principle they would hear but little of excision of the knee-joint. Not long ago he got a hint from an American journal which he found useful in these cases—namely, to keep the leg extended, and thereby prevent the cartilage of the knee from pressing against the femur. This could be effected by placing two or three slips of adhesive plaister from the knee-joint to the foot.

Dr. STAPLETON said he thought Mr. O'Ferrall deserved great credit for the valuable suggestion of deep incisions down to the great trochanter in hip disease. The greater number of diseases of the joints commenced, not in the cartilages of the joint or in the synovial membrane, but in the cancellated structure.

If Mr. Kirkpatrick meant to say that where the disease was commencing in the cancellated structure of the bone he would cut down, divide the periosteum, and introduce caustic, he would reply that if caustic were introduced into the cancellous structure, they could not tell how far it would extend the area of the mischief. He saw a case once with the late Dr. Banon in the Mountjoy prison, in which case, an incision of six inches down to and along the tibia where the periosteum was thickened, gave the greatest relief. Where there was great tension much good would be effected by relieving the tension. He had seen cases where matter was formed in what was once a joint; he had cut freely into it and let the matter out, then put on a splint, and sent the patient out with an ankylosed joint. A case once occurred under his care in which there was disease of the tarsus. He brought down all the requisites for performing an operation, but when the patient saw the instruments he got frightened, and went away. Sometime afterwards, when the Crimean war had terminated, while driving through town, a soldier ran over and caught his horse's head, "Don't you recollect me, sir," said he, "I'm the boy that you were going to operate on." He then stated that he had gone to Clontarf, remained quietly there, and his foot got better, and he was allowed to enlist. The marks of the cicatrices were there, but the man was cured.

Dr. FLEMING said he had had an opportunity of witnessing the progress of these cases in Steevens' Hospital, and of seeing the operations performed, and he thought the society was much indebted to Dr. Macdonnell for bringing them before the Society this evening.

Dr. MCDONNELL, in reply, said the cases he had brought forward owed their interest to their being common. Dr. Kirkpatrick had spoken of his mode of treatment as a preventive measure. Now, although he was very anxious that every fair opportunity should be given of testing it, he thought it was difficult to have recourse to that method as a preventive measure in many cases. No person knew better than their President how insidious these diseases were. Professor Hargrave spoke of intense pain; but none of the cases he had shown that evening were accompanied with intense pain. They belonged to that class where the disease occurred in the cancellated structure, and was not accompanied with pain. People affected with this disease did not generally complain of pain; they complained rather of fatigue; they sit down and say their knee is aching and tired. Persons thus affected would walk about for a long time with the aid of a stick. Now, if in cases of this disease, they were to have recourse to caustic when were they to apply it. He should be very unwilling, while as yet there was no abscess, and the joint was capable of being flexed and extended to cut down, and bore in and burn out the diseased part. That was the practical point to consider. He did not think this was an example of the knee-joint as described by Brodie. It was rare to have a joint where one side was more diseased than another, where the cartilage was firmly attached to the bone on the one side, and gone on the other, one-half of the joint being very nearly healthy, while the other was in an advanced condition of disease. They all knew that in the treatment of these cases in the early stage, rest was most important, and the maintenance of the patient's strength, giving them good food, cod-liver oil, and wine. As a preventive measure, he would rely on these means rather than adopt a treatment which was not free from pain, and which might gain for the surgeon what the discredit of causing that which was the natural result of the disease.

Mr. B. WILLS RICHARDSON then read the following paper:—

IMITATIVE TUMOUR OF THE BREAST—ADENOCELE OF BIRKETT.

Mr. PRESIDENT,—The specimens I have the honour to exhibit to the Society, were taken from a tumour Dr. M'Dowel asked me to examine a few weeks ago.

The tumour was removed from the breast of a young girl, and was so excellent a specimen of the mammary glandular tumour of Paget,—the chronic mammary tumour of Sir A. Cooper, that I preserved some sections of it, four of which are under the microscope upon the table.

In these sections the lobulated appearance is very well marked, each of them appearing to be covered by small lobular projections, which are filled by nuclei and nucleated cells, like the similar structures found in the acini of glands. The cells, however, are not very distinctly seen with the glass beneath which they are placed, it not being of sufficient amplifying power for the purpose.

He should have observed that the tumour itself was enclosed in a strong cyst, which isolated it from the surrounding gland substance.

When cut, the tumour looked like mammary gland, was pale in colour, remarkably firm, but was free from fat.

I am unable to throw any light upon the point of departure or mode by which the pseudo-glandular tumour commences. Notwithstanding, I am inclined to the opinion, that it is congenital, and that the breast at birth contains the nidus for its development, which remains latent for a varying period, in some persons becoming active sooner than in others.

If I might venture to suggest a new name for the mammary glandular or adenoid tumour, I think the term *imitative*, if applied to it, would be useful in a didactic point of view, owing to its more or less perfect simulation of the gland structure.

Before the members examined the specimens, I should mention that they are not their natural colour, having been stained with Beale's carmine fluid, and a solution of aniline black in acetic acid. I have found that if scetions of certain tumours are first stained with the carmine, and then subjected, for four or five days, to the action of a few drops of the aniline black solution in glycerine, they are much improved in colour, becoming of a rich crimson. Indeed, he has several must instructive sections of tumour, stained with the acetic acid solution of aniline black alone.

The meeting then adjourned.

MEDICAL SOCIETY OF LONDON.

MONDAY, JANUARY 20, 1868.

Mr. HENRY SMITH, President, in the Chair.

DR. SANSOM read a case illustrating the use of the ophthalmoscope in medical diagnosis. A boy aged 11, came under his care at the Royal Hospital for Diseases of the Chest, suffering from emaciation and signs of incipient pulmonary tubercles. Besides these signs, there occurred daily headaches of such extreme intensity as to give rise to the fear of tubercular meningitis. By ophthalmoscopic examination, however, the fundus of each eye was found paler, and the vessels smaller than is normal. There was also an exact similarity in the appearance of each. Dr. Sansom considered that the absence of hyperæmia, and the perfect agreement of the signs on each side negatived the idea of intracranial tubercle. Under the influence of cod-liver oil, bromide of potassium, and iron, the boy steadily improved, and the headaches are now passing away.

The PRESIDENT exhibited the metatarsal bones which he had removed in a partial secondary amputation of the foot. The patient had had his toes removed some time since, in consequence of frost-bite, and the stump never healed. He, therefore, laid open the part, and removed a further portion of the foot, and on examination it was found that there was a cavity extending down the centre of the metatarsal bone of the great toe, which had no doubt prevented the union of the stump.

Mr. GAY then read the paper of the evening, on "Varicosity in Relation to Ulcer." He commenced by saying that his classification of ulcers was based on the pathology of the disease. He divided them into three classes: 1st, the idiopathic; 2nd, the venous; and 3rd, the arterial. The first variety, he said, depend on some peculiarity, local only, of the vascular system, and was usually situated between the ankle-joint and the calf of the leg. In the treatment of this, the author advocated rest, and if the ulcer became chronic, and its base thickened, recommended a lotion of nitric acid and opium, or even, in some cases, a blister to the part. The typical form of this ulcer was "the broken skin." In speaking of the second variety or "venous ulcer," the author said, this was frequently associated with a peculiar bronzing of the skin, which might be traced to obstruction, by clot of either the siphenous vein or the deep venous trunks generally of the latter vein. In treating this form of ulcer, Mr. Gay recommended free elliptical incisions along either side of the ulcer, as being the only plan to ensure a permanent cicatrization. The author then dwelt on the so-called "varicose ulcer," and spoke of the complete uselessness, as he thought, of the spiral bandages. He said that, as a rule, varicose veins are not endowed with valves, and that in the veins in which they do exist, the current of blood is not interrupted by the valves. The bandage, on the other hand, does interrupt the current of the blood. He then passed on to the third variety of ulcer, "the arterial," which might invariably be traced to disease of the

arteries, especially of the anterior and posterior tibial. This ulcer very often occupies the whole of the leg, and spreads so as to invade every structure with which it comes in contact. Amputation in such cases is a very hazardous proceeding. Rest and opiates were the most suitable remedies.

In the discussion which followed, the President, Mr. Bryant, Dr. Head, Mr. Adams, and others, took part.

Correspondence.

DR. SINCLAIR AND MR. PHELAN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your journal of the 15th ult., Mr Phelan, adverting to my communication to you of the 18th of December last, states that I therein intimated he had "made an attack on the Rotundo Lying-in Hospital," in the paper which he published in the February number of the *Dublin Quarterly Journal* for 1867. He likewise asserts, that I have, in that same letter to you, accused him of having "brought forward the statistics of the Rotundo to prove the baneful influence of lying-in hospitals, and excluded those of the Coombe in a remarkable manner;" lastly, that I have stated he had "made it appear that the Rotundo is chargeable with increasing the immorality of the city." These three accusations are denied by Mr. Phelan in his letter to you of the 15th ult.; to which letter, so characteristically ingenious, you will, perhaps, allow me an opportunity of replying.

First I shall state what I *really did* say on these topics in my letter to you of the 18th of last December. You may remember, in that communication, my having sketched a letter which I considered would have been an appropriate one for Dr. Kidd to have addressed to Mr. Phelan, after having perused the paper the former had received, for publication, from the latter. It is from this apocryphal note Mr. Phelan has collected these three accusations.

With respect to the first, I made Dr. Kidd—the Editor of the *Dublin Quarterly Journal*—as it were, thus address Mr. Phelan—"You may say what you like respecting the Coombe and the Rotundo in connection, as lying-in hospitals, but in my (Dr. Kidd's) journal I should not like anything to appear, *which might be considered as a marked attack upon* the latter."

With reference to the second accusation, I put the following words into Dr. Kidd's mouth: "You (Mr. Phelan) will observe that you have brought forward the statistics of this hospital (Rotundo) in your endeavour to prove the baneful influence of lying-in hospitals, and have excluded those of the Coombe in a remarkable manner; yet, you must know, that the Coombe comes under the same objections."

The third accusation is contained in the continuation of the sentence last quoted, as follows: "but, moreover, you make it appear that the Rotundo is chargeable with increasing the immorality of the city."

Another quotation from the same source might be construed into a fourth accusation, viz., where I say, "In fact you, Mr. Phelan, appear in the main portion of your argument, *reticent concerning the Coombe, and seem to throw all your shafts against the Rotundo*;" but of this Mr. Phelan takes no notice. That the opinions embodied in the above so-called accusations are held by me, and, I may say, by my "seven associates," I have no hesitation in asserting, and I shall now endeavour to prove, that such opinions are not unfounded.

The first and second accusations I shall take conjointly, for if guilty of the second, I shall make it apparent that Mr. Phelan cannot be innocent of the first.

Mr. Phelan's paper in the eighty-fifth number of the *Dublin Quarterly Journal* pretends to consider "The comparative advantages of affording obstetric attendance on poor women in lying-in hospitals and in their own homes."

He attempts, in this paper, to prove that home treatment for lying-in women is preferable to the treatment of such in hospitals, on account of the immunity from disease and death amongst those delivered under the former system as compared with those "confined" in hospitals, puerperal fever and contagion being the chief causes of mortality amongst the inmates of the latter. For this purpose he makes some cursory allusions to English and foreign statistics, but relies chiefly upon those of Dublin, with which latter he naturally fancies he is personally more familiar, in consequence of his position as Secretary to the Board of Superintendence of the Dublin Hospitals.

It is essential your readers should bear in mind, the better to understand my argument, that there are two lying-in hospitals in this city, the Rotundo and the Coombe.

Now, this paper of Mr. Phelan's, to which I would beg leave to refer your readers (in the eighty-fifth number of the *Dublin Quarterly Journal*), runs over 22 pages—*i.e.*, from page 71 to page 92.

The following is an analysis of its contents:—One page and a-half is devoted to selections from the Registrar-General's reports. Two pages contain statistical results from Mr. Simon's reports, and half a page is taken up with some statistics from the work of M. Leon Le Fort.

There are, then, four pages of the twenty-two occupied by what may be termed preliminary matter, or rather data prefatory to his onslaught.

The remaining eighteen pages will be found to be consumed for the most part as follows:—More than *two pages* are taken up with extracts from Mr. Simon's sixth report to the Privy Council. These extracts contain opinions rather condemnatory of lying-in hospitals, and make special allusions to the Rotundo Hospital. Upon reading one of these quotations, as given by Mr. Phelan, page 77, *Dublin Quarterly Journal*, No. 85, one would suppose that Mr. Simon had, in it, made no allusion to "the other Lying-in Hospital" of Dublin, as the quotation from his report *has not been faithfully quoted by Mr. Phelan*—not to mince matters—*it has been uncandidly stated by him.*

In the original, Mr. Simon has, with his accustomed justness and accuracy, shown, that the very large death-rate which occurred during a certain year in the Rotundo Hospital, was more apparent than real. He also informs us that the chief cause of mortality during that year—puerperal fever—*was not confined to the Rotundo, but likewise prevailed in the other Lying-in Hospital, and was rife throughout the city.* All these matters, which ought to have appeared in the middle of the quotation from Simon's report, have been omitted by Mr. Phelan without acknowledgment; the two ends of the paragraph having been brought together, to make it appear as if the first half and the last were directly continuous. Therefore, the public are led to believe, from the quotation thus given, that puerperal fever was to have been met with *only* at the Rotundo Hospital during this period; and, no doubt, this was the idea Mr. Phelan intended to impress upon his readers, *for it is idle to suppose that this misquotation was not intentional.*

To continue the analysis.—Extracts from a paper by Dr. Telford, in which that gentleman gives an account of an epidemic outbreak of puerperal in the Rotundo hospital, occupies *two pages.*

The partial consideration of the question, as to the effect certain modes of admission may have upon the health of lying-in hospitals, illustrated *solely* by the prevailing custom of the Rotundo hospital, fills *nearly four pages.*

Now comes a remarkable paragraph, which occupies nearly a quarter of a page. It contains a statement to the effect that, according to Johnston and Sinclair, 67 mothers died in the Rotundo Hospital, after purely natural labour, 41 of which succumbed to puerperal fever. Here the author omitted to state that this mortality extended over a period of seven years, and as many as 11,876 deliveries; also, that of this number, though classified under the head of purely natural labour, *i.e.*, those labours in which the head was the presenting part and which were delivered at or within twenty-four hours without instrumental assistance, many were, nevertheless, in an unhealthy condition from various causes. On the contrary, Mr. Phelan states that "as their labours were *natural*, they did not go to hospital on account of malformations, or from apprehension of difficult labours," thus leading the public at large (for whom, it appears to me, Mr. Phelan chiefly writes) to believe that all these women were robust and healthy. What a terrible revelation—sixty-seven robust and healthy women lost *in the Rotundo Hospital after purely natural labour*, 41 of which died of puerperal fever—this *artfully* worded sentence, contains, *for the non-professional reader.* In my opinion this was so arranged to create a hostile sensation against the Rotundo. In the same page (86, *Dublin Quarterly Journal*, number 85), appears a paragraph, nearly half the length of that page, commencing thus:—"The high mortality in lying-in *and other hospitals*, and its frequent occurrence, will be perceived by the table at page 92."

On turning over to page 92, the last of this peculiar production, *its whole length* will be found occupied by a table, judiciously arranged, (as all Mr. Phelan's statistical tables are), showing the death-rate of the women and children *in the Rotundo Hospital only*, (though no heading exists to show from

whence the data have been collected) from the year 1760 to 1864. Then comes the "*application*" of this table, thus, "applying the foregoing returns," (*i.e.*, those deduced from the table at page 92), "and observations to the Rotundo Hospital, we see, &c., &c." Applying the Rotundo Hospital's own statistics to the Rotundo Hospital, *to show "the high mortality in lying-in and other hospitals*!"

Did Mr. Phelan write under the impression, that his readers would not give themselves the trouble of turning over the leaves to look at this table at page 92. Some, he must have been aware, would do so; and they, of course, could not arrive at any other conclusion, than that this table did not afford the information Mr. Phelan had asserted was to have been found there.

At page 88, evidence is given of infectious fever being occasionally introduced *into the Rotundo Hospital*, and the question is mooted as to the effect such introduction may have upon the origin of puerperal fever; all this is argued in connection with the Rotundo Hospital *only, for one page.*

At page 89 "the mortality of children in lying-in hospitals" are asserted to be given; but the only data bearing upon this point, are those derived from the Vienna Lying-in Hospital, the census of Ireland at large, without naming special institutions, and, minutely and particularly, the infant mortality of the Rotundo Hospital.

At page 90 is given a table *which fills that page*, "showing the mortality of children born in the Rotundo Lying-in Hospital under different masters, and the proportion of such mortality to the number of children born alive."

At page 91 a statement is made relative to "still-born children," viz.—the proportion of such to the births at large. Here are given the statistics bearing on this point: of the Austrian dominions, of Trieste, and of the Vienna Lying-in Hospital; but the statistics of the Rotundo *are the only home data mentioned.*

Reviewing the matter contained in this paper of Mr. Phelan's, as carefully as possible, I may fairly state, that of the 18 pages I was bound to account for, 14 (under the mark) are altogether taken up with remarks relative to the Rotundo Lying-in Hospital.

I shall now turn to the other side of the picture.

One page (71, *Dub. Quar. Jour.*, No. 85), the first, of the paper is occupied by statistics to show that the "other lying-in hospital" does proportionally more on a smaller income than the Rotundo. This is most ingeniously managed, under the plea of attempting to prove that home attendance is cheaper than hospital treatment—*a fact not requiring proof.* In addition to this page, one line and a-half, at page 47, is devoted to the statistics of the Coombe Hospital, as follows—"During these seven years 3142 deliveries took place in the Coombe Lying-in Hospital, and 45, or one in 70, died;" and two lines more, stating the Coombe's extern mortality, at page 75. This is the amount of prominence given to the Coombe's statistics by Mr. Phelan; while I have demonstrated that almost fourteen pages, out of eighteen, have been occupied by those of the Rotundo Hospital, and I shall presently show that *nearly three more* are consumed upon the same theme, making nearly 17 out of the 18 I had to account for.

I now inquire, am I not correct in stating that Mr. Phelan has "brought forward the statistics of this hospital (Rotundo) in his endeavour to prove the baneful influence of lying-in hospitals, and" has "excluded those of the Coombe in *a remarkable manner*?" And, moreover, does not Mr. Phelan "know that the Coombe comes under the same objections as the Rotundo?" Why has this partiality been exhibited?

Again, when the animus, so apparent throughout this paper, as exemplified in the unfair way in which statistics are used to suit his purpose, and the manner in which quotations have been tampered with for a similar reason; when, I say, this animus is added to the evident gibbeting he has given the Rotundo Hospital, am I, or are "my associates," wrong in arriving at the conclusion that, in addition to partiality, Mr. Phelan has been guilty of "making an unfair and insidious attack upon the Rotundo Hospital?" Before I proceed to the consideration of the third accusation, I must say a word or two, touching my "*puerilities.*" I demand an answer from Mr. Phelan with respect to a few of them. For example—

Why were the quotations from Simon so *modified*, especially that one at page 77 of the paper, and to which I have made particular allusion?

Why were Johnston's and my statistics of natural labour, stated in the manner in which they are to be found at page 86 of his paper?

When he was endeavouring—if such really was the case—*to arrive at the truth of the important subject concerning which he was writing*, why did not Mr. Phelan give the statistics of the other lying-in hospital as regards epidemic and sporadic puerperal fever; the mortality of natural labour; the death-rate of children; the proportions of still born to the births at large, &c.?

Are the modes of admission into the Coombe so different from those in connection with the Rotundo, as to preclude the possibility of any ill effects from the occasional accidental admission of contagious diseases to the wards of the former? One would suppose, from Mr. Phelan's silence on this point with regard to the other Dublin Lying-in Hospital—his reticence regarding the Coombe—that the Rotundo Hospital was singular in this respect. Why did not Mr. Phelan place a table of the mortality of the Coombe beside that of the Rotundo Hospital?

Now, with respect to the third accusation, "moreover" he makes "it appear that the Rotundo Hospital is chargeable with increasing the immorality of the city." To this Mr. Phelan replies—"I deny that there is one word in my paper *charging the Rotundo, or its authorities, with increasing the immorality of the city, and Dr. Sinclair has not quoted any.*" Now, I never stated Mr. Phelan *did* say anything *directly* of this nature in his paper. He is too experienced a hand at the formation of his productions to commit himself thus, but *I do now assert he has made it appear* that the Rotundo Hospital increases the immorality of the city. I shall go farther and say, that in my opinion—an opinion by no means singular—Mr. Phelan intended this odious impression should get abroad, and have upon society the effect he aimed at producing. That Mr. Phelan makes it appear the Rotundo Hospital increased the immorality of the city, I shall now endeavour to demonstrate.

At page 84 of Mr. Phelan's paper he says:—"Dr. Shekleton's evidence shows that the abandoned, as well as the virtuous, could take advantage of the hospital" (the Rotundo) "and that *no rule, or bye-law, existed to check the repeated admissions of women of the former class*, and I am not aware that any now exists. It is true, as before observed, that when, and long after, the hospital was founded, there was no workhouses to which the immoral class could have recourse when about to be confined; but for many years before that evidence was given they were admissible into all the Irish workhouses as paupers. The *necessity*, therefore, that existed for the admission of this immoral class had long ceased in 1854, and their admission cannot, nor could not, be fairly deemed an act of necessity, nor of charity. *Viewing the subject in a moral sense, it appears likely that such women would be more checked in their career by being compelled to have recourse to the workhouse, where they would have less, though still sufficient, comforts than if received into a superior institution where the stigma of their habits is much concealed.*" What are the most natural inferences for the public to draw from this quotation? Surely it is not unreasonable to suppose they would be as follows:—

First. Women of the immoral class, were they *compelled* to enter the poorhouse for their confinements, would have but limited comforts, and the stigma of their habits would not be altogether concealed; in other words, their immoral condition would be made apparent to the other inmates by some means or other. The immoral class, therefore, if they knew they would be forced to enter the poorhouse, when illegitimately pregnant, would be less likely to incur the risk of illegitimate pregnancy, and so crime would be checked.

Second.—The Rotundo Hospital admits this immoral class; affords the members of it every comfort within its means, which comforts are much superior to those of the poor-house; above all, the poor traviata, or the seduced and "abandoned" one, experiences in the Rotundo not only the comforts of a home, but the kind sympathy of all around her, *more especially exemplified in the silence that is there maintained regarding the past.* Therefore, the Rotundo Hospital does not tend to lessen immorality by such solicitude.

Third.—The immoral woman who illegally incurs pregnancy, knows she can obtain easy admission into the Rotundo when her labour approaches; so that she is not only unarrested in her career of sin, by the inevitable prospect of the poorhouse, but by her means is disseminated the knowledge of this facile admission into the Rotundo, and so that hospital, holds out, as it were, a premium or incentive to immorality.

On the whole, then, I do not think that my idea concerning the meaning Mr. Phelan intended to convey, by the detail of his view of the question "in a moral sense," is unreasonable;

and it is my opinion, as well as that of my "seven associates," that he intended to spread this impression throughout the country.

And now, may I ask, why did this gentleman, in discussing the "moral" aspect of his subject, allude *only* to the Rotundo for the length of *nearly three pages?* Does the other lying-in hospital decline admission to the immoral class? Are the wretched "abandoned" who apply at its door for shelter and aid during "nature's hour of trial," cast off, because they cannot prove themselves *moral* women? Surely not.

If such are not refused admission there, *why then was one hospital held up to public odium in this respect, to the exclusion of the other?*

Towards the conclusion of Mr. Phelan's letter, he thus expresses himself—"If Dr. Sinclair and his seven associates consider this question practically and cooly, they will be attended to, and will do much good; but they cannot prevent the subject from being discussed," &c. With regard to this observation, I beg leave to state on my own behalf, that had I the power to prevent discussion on this important topic, I should refrain from exercising it. In my pamphlet, which was refused admission into the *Dublin Quarterly Journal, I took up no particular side or principle.* I merely exposed what I considered to be shallow and unsound reasoning; too evident bias; and the unfair use of statistics and quotations to support that bias. In fact, as I say at the termination of my pamphlet, "It has not been my object in this paper to *enter minutely into the question at issue, but merely to protest against the manner in which Mr. Phelan has brought the matter forward, especially in connection with the Rotundo Hospital.*" I have merely, in that pamphlet, put the subject *in a proper train for discussion, and I shall be ever ready to argue it, with any one, both coolly and impartially.* I shall, however, expose, to the best of my power, *such unfair and partial writers as Mr. Phelan.*

In conclusion, sir, I cannot avoid quoting a passage contained in a letter I have just received from a most eminent physician, with reference to Mr. Phelan's paper:—"Rash and inconsiderate talking, by members of the profession *who have the public ear*, is one of the *poisons* of the times."—I remain, sir, your obedient servant,

E. B. SINCLAIR.

28, North Frederick-street, Dublin,
January 24, 1868.

[As our readers are now in full possession of information to enable them to arrive at a decision, and having accorded ample space to the communication of all parties, we must here bring the correspondence to a close.—ED. M. P. & C.]

Medical News.

UNIVERSITY OF CAMBRIDGE.—The Linacre Professor of Anatomy and Physiology (Dr. Rollerton) having been prevented from entering upon his courses of instruction on the day mentioned in the notice already issued, commenced the course on Thursday last, February 6, at 1 P.M., which will be continued on Mondays and Thursdays, at the same hour. The practical classes will be carried on with the lectures in connection with them, as in former terms.

APOTHECARIES' HALL.—Dr. Charles Taylor, M.D., St. Andrews, has been elected a member of the Court of Examiners of the Society of Apothecaries; and Dr. Robert Norton, M.D., King's College, Aberdeen, M.R.C.P. London, has been elected chairman of the Court of Examiners, in the vacancies caused by the death of Dr. William George Thisselton Dyer, St. Andrews, L.R.C.P.Edinburgh.

List of Entries in the Register of the Branch Medical Council (Ireland), for the month of January, 1868:—

William Todd Burr, 79, Lower Mount-street, Dublin, M.B., 1867, and Mastr.-Surg., 1867, Univ., Dublin; Nicholas Flanagan, Cellbridge, co. Kildare, Lic. Apoth. Hall, Dublin, 1823; Hugh Brady White, Kilmoylan, Pallas-green, co. Limerick, Lic. R. Coll. Surg., Irel., 1867, Lic., 1867, and Lic. Midwifery, 1867, K. Q. Coll. Phys. Irel.; William Henry Dodd, Killorglin, co. Kerry, Lic. R. Coll. Surg. Irel., 1867, Lic., 1867, and Lic. Midwifery, 1867, K. Q. Coll. Phys. Irel.; Thomas Faris, 15, Upper Gloucester-street, Dublin, M.B. Univ. Dub., 1867, Lic. R. Coll. Surg. Irel., 1867; Joseph Johnstone Monteath, 1, Clyd-terrace, Belfast, M.D. Q. Univ. Irel., 1867, Lic. R. Coll. Surg. Edin., 1867; Patrick Richard Martin, Clogheen, co. Tipperary, M.D., 1867, and Mast.-Surg., 1867, Qu. Univ. Irel.; James Henry Reynolds, 44, Lower Gardiner-street, Dublin, M.B., 1867, and Mast.-Surg., 1867, Univ., Dublin; James Philpot Webb, 7, Pembroke-street, Cork, Lic. Apoth. Hall, Dublin, 1867, Lic. R. Coll. Phys. Edin., 1867; John Walker, Portstewart, co. Londonderry, M.B., 1867, and Mastr.-Surg., 1867, Univ., Dublin; George M'Bride Davis, Newry, co. Down, M.D., 1866, and Mastr.-Surg., 1866, Q. Univ. Irel., Lic. Apoth. Hall, Dublin, 1866; Duke Parke, Cashell House, Derrygonnelly, co. Fermanagh, Lic. R. Coll. Surg. Irel., 1866, Lic. R. Coll. Phys. Edin., 1866; John Francis Fitzpatrick, Mallow, co. Cork, M.D., 1867, and Mastr.-Surg., 1867, Qu. Univ., Irel., Lic. Midwifery, K. Q. C. P. I., 1867, Albert Halahan L'Estrange, 4, Belgrave-road, Rathmines, co. Dublin. Lic. R. C. Surg. Irel., 1867, Lic. 1867, and Lic. Midwifery, 1867, K. Q. Coll. Phys. Irel.; Francis Adolphus L'Estrange, 4, Belgrave-road, Rathmines, co. Dublin, Lic. R. C. Surg. Irel. 1867, Lic. 1867, and Lic. Midwifery, 1867, K. Q. Coll. Phys. Irel.; Peter Thomas Frazer, Donaghmore, Queen's County, Lic. 1867, and Lic. Midwifery, 1867, K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel.; Daniel Thornton, 27, Hardwicke-street, Dublin, Lic. 1867, and Lic. Midwifery, 1868, K. Q. Coll. Phys. Irel.; Thomas Edward Carroll, Knockbridge, co. Louth, Lic. 1867, and Lic. Midwifery, 1867, K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel., 1867; George Edward Dobson, Edgeworthstown, co. Longford, M.B., 1867, and Mastr.-Surg. 1867, Univ. Dublin; Albert Kirwan, 44, Mountjoy-square, Dublin, Lic. R. Coll. Surg. Irel., 1867, Lic. 1868, and Lic. Midwifery, 1868, K. Q. Coll. Phys. Irel.; Frederick Robert Patterson, 14, Landstown-road, co. Dublin, Lic. 1868, and Lic. Midwifery, 1868, K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel., 1867; Olwar Stokes Eagar, The Terrace, Tralee, co. Kerry, Lic. R. Coll. Surg. Irel., 1867, Lic. 1868, and Lic. Midwifery, 1868, K. Q. Coll. Phys. Irel.; William Charles Gasteen, Clonard, co. Meath, M.B. Univ. Dubl., 1866, Memb. R. Coll. Surg. Engl. 1867; Michael Kennelly, 68, Grafton-street, Dublin, Lic. R. Phys. Edin. 1867, Lic. R. Coll. Surg. Edin. 1867, Lic. Apoth. Hall, Dubl. 1865.

CHARLES FREDERICK MOORE, M.D., F.R.C.S.I., has been appointed Medical Inspector of Seamen for the Port and District of Dublin.

HEALTH OF ENGLAND.—The mortality of 1867 was below the average in almost every part of the kingdom. The south-eastern division, as usual, stands first, with a mortality of only 18·90 per thousand for this whole section of the country, taking both bad and good. The south-western, also, as usual, is next, having a mortality of 19·13 per thousand; and then the eastern, 19·33. The several midland divisions follow—the north midland, 20·31; the south midland, 20·32; the west midland, 20·70; and Monmouthshire and Wales, 20·68. The place of London is next, the mortality of 1867 being as low as 22·98; Yorkshire, which has been commonly above London, is on this occasion below it, having a mortality of 23·64 per thousand. The northern division makes an extraordinarily bad return of 24·73 per thousand; but now, as ever, the north-western division (Lancashire and Cheshire) is lowest of all, having to return a mortality of 25·89 per thousand—a return which is a bad one even for this district.

SEAMEN'S HOSPITAL SOCIETY.—The forty-seventh annual meeting was held last Wednesday. The report reviewed the circumstances that led to the introduction of the Merchant Shipping Act of last year, the growing feeling that still exists against the continuance of a floating hospital, and the circumstances by which the locality of their future establishment was still undecided. The financial affairs of the society during the year have been unsatisfactory, "and the Committee are anxious to call attention to the serious fact that, while the annual expenditure has amounted to £8121, the entire receipts of the year have been but £7242, although this includes the sum of £824, the amount received from legacies, which the society was accustomed to invest for its permanent advantage." During the past year 1969 patients have been admitted into the *Dreadnought*; that 1050 have been treated as out-patients, and 156 wholly or partially clothed before their discharge. There were many cases of scurvy, but it is anticipated that this disease will be greatly mitigated by the operation of the Act, which took effect from the 1st of January in the current year, and is now in full working order. The report thus appeals for monetary aid:—"Dependent as we are upon our commerce for the elements of national industry, for a great part of our subsistence, and for the markets for which the products of our manufacturers are destined, it would be needless to show that the strength and prosperity of the country greatly depend upon our seafaring population. A society, therefore, which restores to the service of the merchant marine several thousands of seamen annually must be one deserving of efficient maintenance."

NOTICES TO CORRESPONDENTS.

The following Communications are in type, and will appear in our next:—Phthisis Pulmonalis, by E. J. Kinkead; Incubation of Syphilis, by C. R. Drysdale, M.D.

Letters by—M. Liptrate, R. Griffith, "A Country Doctor," and "One who has Cause to Complain."

HIGHEST PRIZE MEDAL FOR CARBOLIC ACID AT PARIS EXHIBITION, 1867.

F. C. CALVERT & Co., of Bradford, Manchester (original and only Manufacturers of pure Medical Carbolic Acid), beg to inform the Trade and large consumers that their pure Medical Carbolic, as well as cheaper qualities for Commercial, Veterinary, and Disinfecting purposes, also Carbolic Acid Disinfecting Powder, may be had from any of the undermentioned Wholesale Agents:—

Davy, Yates, and Routledge, Upper Thames-street, E.C.
Hearon, McCulloch, and Squire, 5, Coleman-street, E.C.
John Bell and Co., 338, Oxford-street, W.

Harrington and Son, Patrick-street, Cork.

Or of F. C. CALVERT & Co., Tower Chemical Works, Bradford, near Manchester.

NEPENTHE.

PREPARED EXCLUSIVELY FROM OPIUM. (Dose the same as Tinctura Opii.)

Nepenthe does not produce headache, stupor, giddiness, depression of spirits, diminution of nervous energy, prostration of strength, nor constipation, but induces natural and refreshing sleep. It may be used with perfect safety in every case where an Opiate is indicated, and from the peculiar process by which it is prepared it is deprived of all constitutents which render the Tinctura Opii, and most other forms of Opium, in very numerous instances wholly inadmissible. It is always of UNIFORM STRENGTH, and in this respect possesses high advantages.
Price 8s. per lb.

May be procured direct from the Sole Manufacturers,

FERRIS, TOWNSEND, BOORNE, AND TOWNSEND,
Wholesale Druggists, Bristol,

And through all leading Wholesale and Retail Chemists in Great Britain and the Colonies.

Messrs. FERRIS & COMPY.'S New Copyright Price List of Drugs and Chemicals, with complete Table of Doses, will be forwarded to Medical Gentlemen on application.

NATURAL MINERAL WATERS OF VALS, VICHY, CARLSBAD,

Seltzer, Kissengen, Homburgh, Pullna, Friedichshall, &c., direct from the Springs; also the Artificial Mineral Waters prepared by Dr. Struve and Co., at the Royal German Spa, Brighton, and the Natural Bromo-Iodine Water of Woodhall Spa, Lincolnshire.

Agents—W. BEST and SONS, 22, Henrietta-street, Cavendish-square, London, W.

THE NATURAL MINERAL WATERS OF VICHY

have proved always successful in cases of DIABETES, GRAVEL, GOUT, LIVER COMPLAINTS, ACIDITY, &c.
Invalids prevented from going to the springs can follow a regular treatment at home, by drinking the water and using the salt for baths.
Pamphlet and Analysis free on application.
VICHY WATERS COMPANY, 27, Margaret-street, Regent-street, London, W.
Depot for all French and German Mineral Waters.

BOOKBINDING.

M. & J. SULLIVAN are provided with the greatest facilities for executing BOOKBINDING in every style, and in the best manner, *expeditiously*, and with *punctuality*. Their prices will be found the *lowest* in the trade.

*** Special terms for the binding of Libraries, or for lots of 50 vols. and upwards.

M. & J. SULLIVAN,
Educational Publishers, Bookbinders, &c., 27, Marlborough-street, DUBLIN.

SUCCESSOR TO THE LATE WM. THOMPSON OF DAME-STREET,
OUTLER TO THE LORD LIEUTENANT, AND SURGICAL INSTRUMENT MAKER,
18, NASSAU-STREET, DUBLIN,
Adjoining Morrison's Hotel.
Cutlery carefully Repaired.
Surgical and Veterinary Instruments Made and Repaired.

£4:4:0 PROFESSIONAL SUIT in Fine Black, or Oxford Cloth. Fit and quality guaranteed.
21s. ZEPHYR OVERCOATS, Silk Faced, in various colours.

RICHARD SALTER,
MERCHANT, CLOTHIER, AND HATTER,
48, Grafton-street.
(FOUR DOORS FROM STEPHEN'S GREEN.)

TO PHYSICIANS, SURGEONS, AND DRUGGISTS.

Brown's Cantharidine Blistering Tissue, prepared from pure Cantharidine. An elegant preparation, vesicating in much less time than the Emp. Lyttæ, P.L., easily applied and removed, and will not produce strangury or troublesome after-sores. It has received the sanction and commendation of many of the most eminent practitioners in the kingdom.—In tin cases, containing ten feet, 6s. 6d.; and small cases of five square feet, 3s. 6d. each.

BROWN'S TISSUE DRESSING.

An elegant, economical, and cleanly substitute for all ointments as a dressing for Blisters, Burns, &c., and may be called a companion to the above.—In tin cases, containing twelve square feet, 1s. 6d. each.

Sole Inventor and Manufacturer, T. B. BROWN, Perry Barr, Birmingham. Sold by all Wholesale and Retail Druggists and Medicine Agents throughout the British Empire.

Dublin: Messrs. Boileau and Boyd, 91, 92, & 93, Bride-street.

S. TREACY & CO'S HAND-SEWN SHIRTS Cannot be surpassed for FIT and QUALITY.
6 for 33s.: 6 for 39s.: 6 for 45s.
INDIA AND COLONIAL OUTFITS, Ready by Three Days' notice.
Lists Free on Application.
HOSIER, GLOVER, TIE, AND SCARF IMPORTER.
Late Manager to HUNT & Co.
Please observe—24, WESTMORELAND-STREET, DUBLIN.

Dr. LETHEBY'S SECOND LECTURE ON FOOD.

COMPARATIVE DIGESTIBILITY OF FOODS—FUNCTIONS OF DIFFERENT FOODS.

THE phenomena of digestion are altogether of a physical and chemical nature; there is nothing whatever of a vital quality about them; for the comminuted food is brought successively under the influence of special solvents furnished by the saliva, the gastric juice, the pancreatic fluid, the biliary secretion, and the intestinal mucus; all of which are associated with a large volume of water. Digestion, indeed, as Berzelius remarked, is a true process of rinsing—the amount of fluid secreted into the alimentary canal, and again absorbed from it, being, according to the researches of Bernard, Bidder, and Schmidt, not less than three gallons in the twenty-four hours. The following, in fact, are the daily proportions of the several secretions and their solid constituents:—

	Lbs.	Grs. of solid matter.	Grs. of active principles.
Saliva ...	3·54	... 231	... 37 of Ptyalin.
Gastric juice ...	14·11	... 2960	... 316 of Pepsin.
Pancreatic fluid	8·82	... 6172	... 773 of Pancreatin.
Bile ...	3·54	... 1233	... 1073 of Organic Ferment.
Intestinal mucus	0·47	... 46	... 28 of do.
Total ...	30·48	... 10642	... 2227 of Special Solvents.

All of which, by their special solutive actions on the several constituents of food, rob it of its nutritive quality, and carry it into the circulation.

Each of the fluids, so largely secreted into the alimentary canal, has its special functions.

The *Saliva*, which is a secretion from many glands opening into the mouth, is a thin glairy liquid, of slight alkaline reaction, except while fasting; and containing about 1 per cent. of solid matter—half of which is a peculiar organic body, called *ptyalin*, and the rest is composed of chloride and phosphate of sodium, with a little carbonate and sulphocyanide. Ptyalin is a nitrogenous substance, of the nature of diastase—the ferment, which in the vegetable converts starch into sugar, and hence it has been called *animal diastase* by Mialhe, who attaches great importance to it as the principal agent concerned in the digestion of starchy foods—one part of ptyalin, according to him, being capable of converting 8000 parts of insoluble starch into soluble glucose. Saliva has no chemical action on fat, or fibrin, or albuminous bodies—its real functions being to lubricate the food for deglutition, to carry oxygen into the stomach, and to furnish a solvent for starch and tender cellulose. Those animals which feed chiefly on woody matters, as the beaver, have large salivary glands, and provision is made for a prolonged contact of the secretion with the vegetable tissue.

An artificial saliva may be obtained from seeds which have fermented, and in which the diastase is abundant. *Liebig's Extract of Malt* is an example of this; and Mr. Morson has taken advantage of the discovery of M. Mège Mouries, that the inner layer of bran contains a nitrogenous digestive principle called *cerealin*, of the nature of diastase, and has extracted it, and consolidated it with sugar, in a preparation which he has named *saccharated wheat phosphates*. Both of these are aids to the digestion of farinaceous matters.

Gastric juice is a secretion from the entire surface of the stomach. It is a transparent liquid, of a pale yellow colour, and of a saline and acid taste. It is much heavier than water (sp. gr. about 1020), and it contains from 2 to 3 per cent. of solid matter—about 1·7 of which is a remarkable nitrogenous organic body, called by Schwann, its discoverer, *pepsin*. Its peculiarity is, that in the presence of an acid, it converts almost every description of albuminous and fibrinous matter into a soluble form of albumen, called by Lehmann *peptone*, and by Mialhe *albuminose*. It differs from common albumen in many particulars—it is, for example, more liquid; it is not coagulated by heat, nor by weak spirit, nor by acids, nor by most mineral salts; it is not very prone to decomposition; and it is capable of *dialysis*, that is, of transudation through animal membrane, and, therefore, of absorption, which albumen is not. The digestive power of it is very great, for Wasmann found that an acid liquid containing only one part of it in 60,000 of the solution—that is about one grain in a gallon, was capable of dissolving meat; and Lehmann ascertained that 100 parts of the gastric juice of a dog would digest 5 parts of coagulated albumen.

The nature of the free acid in gastric juice is somewhat doubtful; Lehmann, who has frequently examined it, says it is lactic acid, but Schwann asserts that he has often found free hydrochloric acid. It may be that the chlorides contained in the stomach are partially decomposed by lactic acid, especially during the process of analysis, and thus the hydrochloric acid may be accounted for. When the acid is in too large excess, the digestive action is abnormal, and so also when it is deficient; Lehmann states that the best proportion is when 100 parts of the gastric juice is just neutralized with 1·27 of potash.

Considering the importance of pepsin as a digestive agent, the preparation of it has become a common affair of trade. In France it is obtained from the stomach of the pig by carefully washing it, then scraping off the soft mucus membrane, rubbing it down with a little water, filtering, precipitating the foreign matters with acetate of lead, again filtering, and then precipitating the excess of lead with sulphuretted hydrogen, after which it is allowed to stand, or it is warmed, to get rid of excess of sulphuretted hydrogen; it is then filtered once more, and after carefully evaporating to the consistence of syrup it is consolidated with dry starch. In this country it is prepared from the stomach of the sheep as well as of the pig, and we have our *pepsina ovis*, and *pepsina porci*; besides which, the use of lead and sulphuretted hydrogen are avoided, by precipitating the foreign matter with alcohol, pepsin being soluble in weak spirit. On the lecture-table are specimens of Boudault's pepsin, as well as those of Mr. Morson, of London, Messrs. Turner and Co., and Mr. Claridge, of Warwick, all of which are also in operation, showing their relative digestive powers on animal fibrin.

The pepsin preparations on the table contain varying proportions of starch, as from 20 to 50 per cent.; but the digestive power of any specimen may be easily tested by putting a dose of the preparation into a small bottle with half an ounce of water, acidulating with 20 drops of hydrochloric acid, and then adding half a drachm of hard boiled egg chopped small, or the same weight of lean meat, or 120 grains of the fibrin of blood. On standing in a warm place at a temperature of from 100 to 110, the digestion should be complete in two hours. Tried in this manner, Dr. Pavy found, some time ago, that nearly all the preparations in common use were inert; not so, however, at the present time, for, as you will notice, digestion is proceeding rapidly.

I am told that the strongest pepsin is obtained from young healthy pigs which are kept hungry, and are then excited by savory food which they are not allowed to eat; while the influence of it is strong upon them, and the secretions are pouring out in expectation of the meal, the animals are pithed.

Pepsin, like diastase, is rendered inert by a temperature of from 120 to 130° Fah.; and, therefore, very hot drinks after a meal are hurtful.

Pancreatic fluid is a secretion from the pancreas or sweet-bread. Until recently its true digestive functions were not well determined. It is a colourless fluid of a gravity of 1008 or 1009. Like the saliva, it is generally a little alkaline, and it contains about 1·3 per cent. of solid matter, one-eighth of which is a nitrogenous organic substance of the nature of ptyalin or diastase, and is called *pancreatin*.

More than twenty years ago, Bernard proved, what Valentin had long before suspected, that the pancreatic fluid was concerned in the digestion of fatty matters; but he fell into error in supposing that its action was to saponify the fat, and to set free glycerin. Here is a specimen of glycerin and of lead-soap, obtained from fat upon which the pancreatic fluid had previously acted, showing that saponification had not been effected. The true action of the pancreatic secretion is evidently to break up the large granules, and crystals, and globules of oil and fat, into myriads of minute particles of from 1-3000th to 1-15000th of an inch in diameter. In this way the fat is emulsified, and converted into a milky liquid, which mixes freely with water, and passes through the tissues of the intestines into the lacteals. We are indebted for this knowledge to Mr. Julius Schweitzer, of Brighton, who, while managing the laboratory of Messrs. Savory and Moore, made a large series of investigations into the properties of the pancreatic fluid, at the instance of Dr. Dobell, who had long been of opinion that its functions were important in certain diseases, and required elucidation. When the fresh pancreas (and best of the pig) is rubbed down in a mortar with twice its weight of hogs lard, it rapidly emulsifies it; and on adding about four or five times the bulk of water, and straining through muslin, there is obtained a thick milky liquid of the consistence of cream, which gradually consolidates. If this be treated with ether the pancreatised fat dissolves; and when the ether is separated by distillation, there remains the purified pancreatised fat, which is still miscible with water; in fact, when mixed with four or five parts of water it forms the creamy emulsion which is used dietetically and medicinally in doses of a teaspoonful at a time.

The properties of the pancreatic fluid have been well described by Dr. Dobell in a paper recently read before the Royal Society of London; and it would seem that the fluid has not only the remarkable property of emulsifying oil and fat, and so rendering them capable of absorption, but it has also the power of dissolving starch by converting it into glucose. In this respect its action is like that of saliva, but it is much more energetic; for in its fresh state, one part of the pancreas will dissolve eight parts of starch, and even after it has emulsified fat it will dissolve two parts of starch. It is, therefore, a powerful agent of digestion, in so far as fat, and starch, and young cellulose are concerned, but it has little or no action on albuminous substances.

I am indebted to Dr. Dobell and to Mr. Morson for the specimens of *pancreatin* and *pancreatized fat* upon the table. The first of these preparations is obtained by treating the fresh pancreas with water, and carefully evaporating the solution to the consistence of syrup, and then consolidating it with the flour of malt. Perhaps the dried pancreas, powdered and mixed with malt, would be a stronger preparation.

The *Bile* is a complex liquid, consisting of biliary acids (*taurocholic glycocolic*, &c.) in combination with soda. Its reaction is slightly alkaline, and it contains about 14 per cent. of solid matter, not less than 12 of which are organic.

The true function of the bile is unknown; perhaps it aids in neutralizing the acid peptones from the stomach; perhaps, also, in emulsifying fat; and it may be that it helps the digestion of starchy foods. Lehmann thinks it is a rich residuum from the manufacture of blood globules in the liver, and that it is secreted into the alimentary canal, only to be reabsorbed into the blood. Mr. Lee, also, is of opinion, from his examination of the fœtal liver, that it separates a highly nutritious substance from the portal blood, which is elaborated in the intestines. Its functions are evidently obscure.

Lastly, the *intestinal secretion* which is thrown out along the whole course of the small intestines, is, according to the researches of Bidder and Schmidt, a powerful agent of digestion; for it combines the activity and digestive power of all the other secretions—starch, fat, and albuminous substances being all equally well digested by it.

The food, therefore, coming into contact with these special solvents, and being copiously drenched with fluid, gives up its nutritive constituents. Admirable, however, as this provision is for the digestion of food, a considerable portion of useful matter passes through the bowel unchanged; for cellulose, starch globules, and muscular fibre are common constituents of sewage. Dr. Lyon Playfair says that in the case of an adult man, with good digestion, 1-12th of the nitrogen of the food passes away with the fæces, and others have computed it at an eighth. In a dry state the fæces of man contain about 6·5 per cent. of nitrogen, and in the fresh state 1·7. In Ranke's experiments, it was ascertained that the nitrogen in the fæces was to that in the urine as 1 to 12·5. Much of this is,

doubtless, derived from the secretions which have done the work of digestion and have thus become effete ; indeed, Dr. Marcet is of opinion that the alvine discharges are chiefly composed of the residuum of albuminous substances which have been secreted into the bowel for the purposes of digestion. In ordinary individuals they amount to from 4 oz. to 5·5 oz. a-day—(Wehsurg says 4·6 oz.; Liebig, 5·5 oz.; Lawes, 4·2 for a middle-aged adult, and 6·2 for a person over 50—the mean amount for adult males being 4·2 oz., and for adult females 1·3 oz.) ; and when calculated in a dry state they amount to about 1·1 oz. daily. It would seem, however, that when indigestible and irritating food is used, the quantity of fæcal matter is increased, as if the food was hurried through the intestines without undergoing digestion. At the Wakefield Prison, for example, it was found that when brown bread, containing bran, was given to the prisoners, the weight of the fæces was 7 oz. per head daily ; and the same fact has been observed at the Coldbathfields Prison.

With this general account of the digestive function of the different secretions discharged into the alimentary canal we are prepared to inquire into the digestibility of different alimentary substances.

(To be continued.)

LECTURES ON VENEREAL DISEASES

DELIVERED IN

DR. STEEVENS' HOSPITAL.

LECTURE II.

By ROBERT McDONNELL, M.D., F.R.S.,

ONE OF THE SURGEONS TO STEEVENS' HOSPITAL.

GENTLEMEN,—In my last lecture I discussed some topics relating to venereal disease in general, and while attempting to give you a fair and impartial statement of the evidence upon these subjects, I allowed you to see the conclusions towards which I myself conceive that this evidence tends. These conclusions were—

First, that gonorrhœa, the simple venereal sore, and the syphilitic sore, are diseases arising from three distinct poisons.

Secondly, that true syphilis, when propagated by contagion (that is not hereditary), begins its inroad on the day of infection, creeps on in ambush for a fortnight or three weeks of incubation, then declares itself as a dry papule, a chancrous excoriation, or a hard chancre. From this time the disease is no longer capable of being cut short, nor is it capable of being inoculated upon another part of the individual who has it. In other words, it is not abortible, neither is it auto-inoculable. Constitutional syphilis must follow. We have, in fact, to deal with a morbid principle in the system. How are we to deal with it ?

I must now ask you to turn aside with me for a time to look at some general facts with regard to morbid principles, and to consider the tendency which some of them have to take up a permanent residence in the frame, and the tendency of others to make a raid, and after a time disappear.

I would ask you, on the threshold of this part of our inquiry, what do you mean by a diathesis? In truth, it is a singularly indefinite term, indicating a peculiar morbid tendency in an individual. It is not a disease, but a proclivity to disease of a particular kind. It is something which is handed down from parent to offspring for generations. Thus we speak of the scrofulous diathesis, gouty diathesis, and so forth. It is merely another word for disposition, and affords little or no clue to the thing spoken of. Yet, this vague and unscientific term diathesis implies the existence of a morbid principle in the animal economy. A man having met with a compound fracture of the leg is admitted into this hospital from the adjoining brewery. He has been in the habit, for many years, of partaking largely, indeed, excessively, of porter. From his appearance and his history, we know that the accident which has befallen him is likely to give rise to bad results. In fact, we say that his blood is in a bad condition. He is more liable than other persons suffering from a like accident to be attacked by erysipelas, gangrene, or pyæmia. We call such a condition an inflammatory diathesis. We recognise in this individual a morbid principle, residing in his frame and apt to be called into action by the accident which has befallen him. All this is very different from what we observe in cases where a morbid principle or poison is received into the system by infection or inoculation, producing what we call toxæmia, or a true intoxication—a condition in which a struggle ensues between the disease and the constitution of the patient, and nature either succeeds in expelling the poison or dies in the attempt. An individual gets smallpox, measles, or typhus fever. At the moment when the disease declares itself, a commotion takes place in the system. As soon as the constitution recovers from its surprise, the struggle begins, and nature tries to drive out the intruder. Although in one sense all toxæmic maladies are true diseases, yet in another point of view they are processes of health. They are efforts of nature to restore health, and are no more diseases than parturition is a disease. The skilful midwifery practitioner takes his stand at the bedside of a patient in labour, to conduct a process of health often fraught with danger to a happy issue. His skill and experience have taught him to repose confidence in nature's efforts. He does not think of giving ergot in every case, or of having recourse to the forceps or the cephalotribe. In like manner the judicious medical practitioner takes his stand beside the small-pox patient to aid nature in the accomplishment of a certain definite object. The time has gone past for speaking of specific remedies for morbid poisons, such as produce small-pox, measles, or typhus. We no longer believe that there are remedies at present known, which can neutralize these poisons as an acid does an alkali, and which can cut these diseases short. But close observation and experience have taught the medical mariner where the shoals and rocks lie hid. He has learned the days of greatest danger, the accidental conplications, the signs of debility, and he strives, by aiding nature at those periods, to bring his patient safely through the struggle.

Now, gentlemen, the question is, does the syphilitic poison give rise to a diathesis, or is it a true intoxication. Ricord says, "that the induration of chancre is the first symptom of a diathesis," and Diday says, "it is an intoxication, not a diathesis." I conceive that it is a matter of the greatest consequence, yet a matter of the greatest difficulty, to decide between these opposite opinions. Does the poison of syphilis give rise to a diathesis analogous to that of gout, scrofula, rheumatism, &c. ; or is it a toxæmic disease—a true intoxication, a disease like small-pox, tending to spontaneous cure, if nature be strong enough to expel the poison—if the human frame, like the womb of the parent, is able to expel the putrid fœtus. If the first proposition be true, there can be no inherent tendency to self-cure, for a morbid principle has entered the organism there to reside, and this principle engendering a proclivity to disease of a particular kind, will be ever and always ready to be roused into activity. True it may lie dormant for years. It may remain in a state of quiescence while the general health is good, but if debilitating influences, such as insufficient food or clothing, bad air, hardship or debauchery, come to lower the bodily strength, the morbid principle of syphilis may forthwith declare itself. We can never speak of recovery from a scrofulous diathesis. We can never speak of curing a gouty disposition. We can only hope that by following certain well-known rules of conduct, we may diminish the risks to which such subjects are liable. If there is evidence that the morbid principle of syphilis engenders a diathesis, it then must fall within the same category. Just as good air, good food, cod-liver oil, iron may be of use in keeping the scrofulous tendency in check, so certain remedies can exercise a great control over syphilis, may muzzle it; but on the theory of a diathesis, neither the one nor the other can be cured.

Now, if, on the other hand, we have in communicated syphilis a true toxæmia, we have to do with a malady which is spontaneously curable ; that is to say, with one in which nature is able, under favourable circumstances, to grapple with the morbid principle, to seize the intruder by the throat, and after a longer or a shorter struggle to kick him out. If then syphilis belongs to the latter category, we may reasonably hope for a complete recovery. We may speak of cure as we speak of it in any disease of the same class ; that is, we may expect that by aiding nature in the contest we may eventually bring about complete restoration to health.

I have already said that the term diathesis is very vague. Perhaps some may say I am wrong in speaking of it as an incurable condition; but I am sure that, as the word is generally understood, I am right. You will, however, easily see the reason why some eminent authorities have been led to adopt, in the case of syphilis, the theory of a diathesis, while others equally eminent regard it as an intoxication. The long and tedious course which the complaint runs, the disposition which it has to combine with certain known cachexias, the manner in which, after it has apparently gone off, it turns like the retreating Parthian, to take another shot ; above all, its hereditary disposition have caused it not unnaturally to be looked upon as something very different from a morbid poison capable in due course of being eliminated. This view of the subject has been strengthened, no doubt, by the fact that the cachexias arising from debauched habits of life among the wealthy, misery among the poor, and from prolonged and severe specific treatment for the disease itself (cachexias too frequently accompanying syphilis, although essentially distinct from it), have served to mask the true nature of the complaint, and caused the condition resulting from the whole to be regarded as a diathesis.

That syphilis is a toxæmia, a true intoxication, I cannot doubt. Diday's argument on this question appears to me unanswerable, but facts are beyond reasoning on such a subject. When I see a patient with a hard chancre, accompanied by hard glands in the groin, followed by the usual syphilitic sore throat, pains in the bones, affections in the cervical lymphatic glands, several successive crops of syphilitic eruption on the skin; and when I see this patient getting well and years after married, his wife in good health, in good health himself, and the father of healthy children, "Dont" (to use the modest expression of Gil Blas) "it croit pieusement etre le pere." When I know that from the first to the last he has not taken one grain of mercury; that he has been treated on the simplest principles of hygiene, how can I refuse to believe that there has been a poison which has been eliminated, and that health has been as perfectly re-established as after recovery from small-pox or from typhus. This is a subject upon which I do not myself entertain the slightest doubt. I cannot expect, I do not ask you, gentlemen, to adopt my convictions. It is not from the hearing of cases, or from reading, that you can come to be thoroughly convinced upon this important point. You must get your convictions where I got mine, not from the teaching of any man, but from the observation of cases about which I could not be deceived. Let me earnestly beg of you from this time, early in your career, to watch and note those cases which you may reasonably hope to follow for years. If you do so, I venture to predict, with the greatest possible confidence, that the time will come when you will hold as strong convictions as I do this moment regarding the curability of syphilis without the use of specifics.

You must not, however, suppose that because I regard syphilis as essentially a toxæmic disease, I therefore altogether deny the existence of a peculiar cachexia in syphilitic patients. Nature has indeed a long and hard battle to fight in eliminating this poison, and the victory is often won by a constitution which has been so thoroughly exhausted in the contest that it is never good for much after. If in addition to the exhaustion resulting from a fair fight in a constitution not naturally vigorous, we remember that there is not unfrequently a bad condition of health resulting from the debauched habits of life of the wealthy profligate, or the miseries and hardships of the poor, and if with this we connect the evil influences of treatment, which assuredly tends rather to weaken than to strengthen, we can easily account for a cachexia or diathesis being at length formed. What I wish you to understand, what I most desire to put before you in a clear light, is that the intoxication of syphilis and the cachexia which follows, are essentially distinct—that while syphilis itself is a true toxæmic disease, capable therefore of spontaneous cure, it is too often followed by a cachexia, in producing which, debility, debauchery, poverty, and misery have had, perhaps, each a share.

According to Ricord, the drama of syphilis is divided into three acts or parts :—

1st. The primitive accident or chancre, which is the immediate result of contagion.

2nd. The secondary accidents or constitutional poisoning resulting from this infection.

3rd. The tertiary accidents, rarely showing themselves before the end of the sixth month.

To these Bazin has added a fourth, which comprises the visceral lesions, and which he designates under the name of the quaternary period. I would observe, in passing, that it is much to be regretted that such terms as primary, secondary, tertiary, &c., cannot be expunged from among the technicalities of syphilis. They imply that the syphilitic drama consists of so many distinct acts. They give the idea that the curtain must rise and fall so many times before the play is over: in short, that the performance is still unfinished unless tertiary and quaternary symptoms present themselves. All this tends to perpetuate as far as nomenclature can, the old notion that syphilis of itself always gets worse, and never gets better spontaneously.

(To be continued.)

Original Communications.

ON AN IMPROVED SPLINT FOR THE TREATMENT OF FRACTURES OF THE THIGH, AND FOR AFFECTIONS OF THE KNEE AND HIP-JOINT.

By Mr. MORGAN, F.R.C.S.I.,

SURGEON TO MERCER'S HOSPITAL; PROFESSOR OF SURGICAL AND DESCRIPTIVE ANATOMY, R.C.S.I.

NOTWITHSTANDING the many methods adopted for the treatment of fractures of the thigh bone, and the arguments adduced in favour of each, all of them meritorious, and evidencing an ever active anxiety on the part of practical surgeons to attain the utmost perfection of mechanical and scientific aid in the treatment of these very important accidents, I believe there are yet some improvements capable of being made, which overcome objections that may apply in a greater or less degree to the various apparatus in use, and which I hope to have obviated in the adaptation I have arranged and found practically most satisfactory.

The question of the extended position being the most applicable to fractures of the thigh, has been so vigorously debated, and so great a mass of evidence brought forward in its favour, that it may be considered as decided—having gone through various vicissitudes of opinion, as thus epitomized in the most recent work on the subject.

There have been three grand epochs in the history of treatment of fractures of the thigh :—

1st. That in which the straight position was universally adopted, and which reaches from the earliest periods to the period of the writings of Pott.

2nd. The epoch of the flexed position which, inaugurated by Pott, had already begun to decline at the beginning of the present century, and which may be said to have been

AN IMPROVED SPLINT FOR THE TREATMENT OF FRACTURES OF THE THIGH AND AFFECTIONS OF THE KNEE AND HIP JOINTS.

Fig. 1.

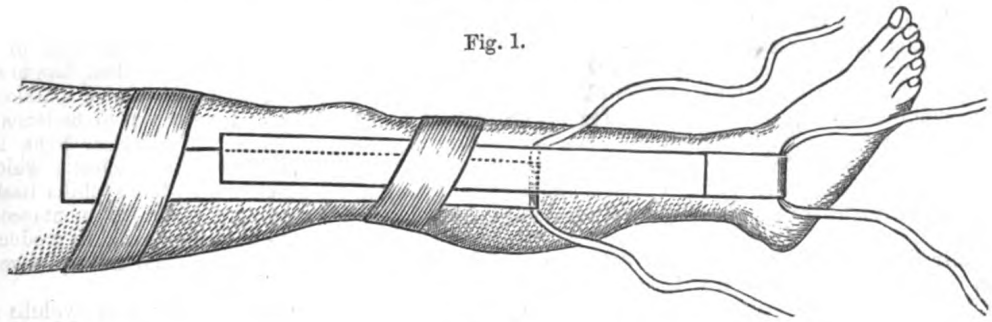

Fig. 2.

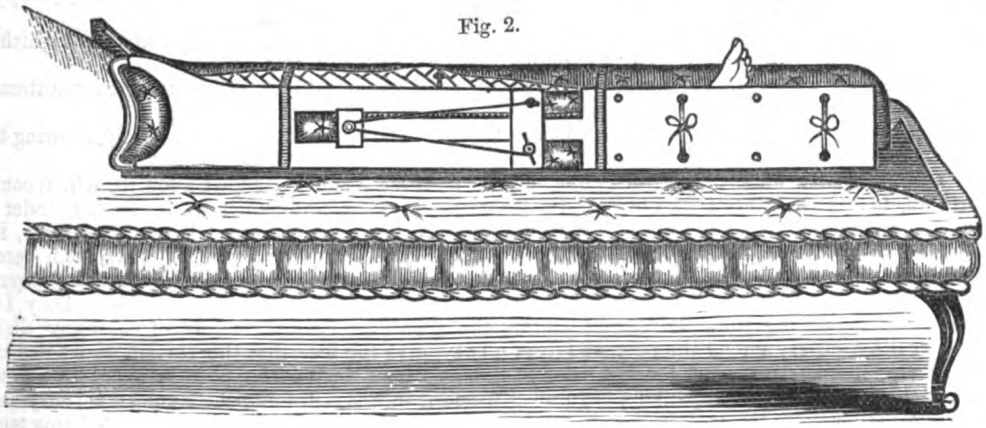

Fig. 3.

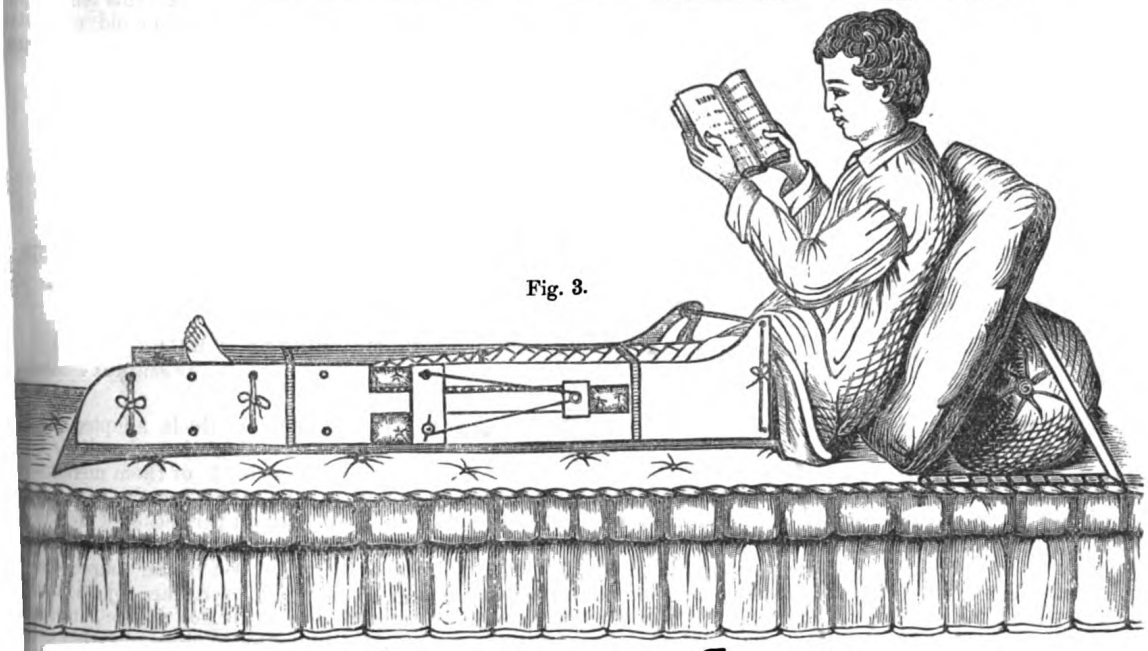

Fig. 4.

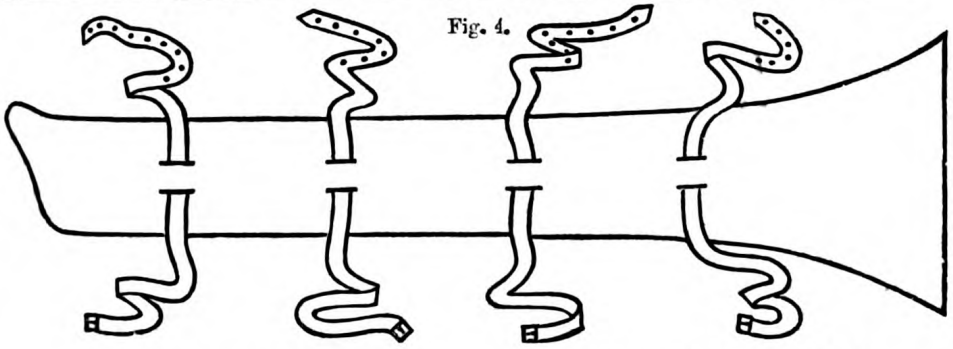

completed within less than 100 years from the date of its first announcement.

3rd. The epoch of *renaissance*, or that in which surgeons, by the vote of an overwhelming majority, have declared again in favour of the straight position—*this is the epoch of our own day.*[1]

The great practical object sought to be obtained has been the most efficient and endurable method of attaining the permanent co-aptation, and keeping in proper position of the fractured extremities, which, specially where they are so frequently oblique, it is of the utmost necessity to have accurately in contact, and subject, during treatment, to a continued and never-yielding extending and counter-extending force, and which, if even momentarily relaxed, would allow the work of reparation to be disturbed, or altogether lost. The difficulties of attaining a thoroughly applicable and satisfactory means of accomplishing this, have been so great that, from time to time, we find surgeons of high repute, expressing their dissatisfaction with the then known means of carrying out the details of treatment.

Chelius, in 1847, remarks :—"The broken ends are retained in their place with great difficulty, and the cure takes place most commonly with deformity, and shortening of the limb, specially in oblique fractures."[2]

Maclise, in his "Surgical Anatomy," remarks :—"Out of every six fractures of either clavicle or thigh bone, I believe that, as the result of our treatment by the present forms of mechanical contrivances, there would not be found three cases of co-aptation of the broken ends of the bone, so complete as to do credit to the surgeon."

J. Bell declared, "the machine is not yet invented by which a fractured thigh-bone can be perfectly secured."

Nélaton mentions the "shortening of the limb, which it is almost impossible wholly to prevent."

No less eminent a surgeon than Dr. Mott is thus reported to have given evidence in a court of law :—"More or less shortening of the limb is uniformly the result after fractured thigh, even in the most favourable circumstances."

It is, therefore, not surprising that so much attention has been directed to attain a perfect method of treatment.

That I now propose will, I think, accomplish it with much comfort to the patient, and satisfaction to the surgeons. I propose to do away with the chance of compression on the foot, heel, or ankle, so often complained of by the patient, specially rendering young subjects irritable and distressed, causing chafing of the skin, puffing of the integuments, and involving the necessity of keeping the foot bandaged, and more or less immoveable and compressed during the entire treatment, whether in the ordinary Liston's splint, or its admirable modification by Butcher, or in splints where a boot is used with a screw as the extending force ; and particularly in such cases, though rare, where injury or previous disease would not allow of the application of a bandage as a means of fixation or extension, as in the case referred to by Hamilton, where, from the inability to use the bandage, owing to an ulceration of the heel, the fracture was *allowed* to unite with two and a half inches of shortening. The means of extension I use is by the medium of good adhesive plaster straps on each side of the limb, beginning below the site of the fracture. Various have been the claimants for priority in the using of this simple and very efficient means of giving a *diffused* traction over the limb. I have found it most satisfactory, and capable of exerting an amount of power which, without trial and practical experience, might appear incredible. I am borne out, I am sure, in this statement by all who have tested the method, and by the following extract :—"The adhesive plaster bands are beyond all comparison the best means of making permanent extension, which are at present known to the surgeon."[3] My colleague, Mr. O'Grady, having seen the method largely used in the United States hospitals, has adopted it in the treatment of many cases of fracture and found it always most satisfactory and successful. By this means there is no difficulty in obtaining a powerful purchase on the limb, without danger of irritation, swelling, or causing pain by constriction. One, two, or three straps may be applied with a special extending force from each, but two broad straps, about three and a half inches wide, of well made adhesive plaster, generally suffice ; a lap of three inches or more of the end of the strap is made round the centre of a piece of stout tape, and least it should, by possibility, slip, a few stitches may be inserted—or the strap itself tied to the centre of the tape, the ends of which are brought out at the slits made in the splints, and tied after the application of the plaster to the skin ; this should be carefully done without wrinkling, one strap reaching from immediately below the seat of the fracture to the middle of the calf of the leg, another from below the knee to the ankle ; thus traction will be exerted from both above and below the knee ; the foot by this method is left perfectly free ; it is not bound or pressed backwards or laterally, and the patient has the relief of not having it retained in any constrained position (Fig 1). As a means of counter extension I have the inner splint cut out at the top in a half circle, and a piece of $\frac{5}{8}$th or more india-rubber tubing strained across from each horn of the half circle ; this india-rubber acts as the lac, and, being elastic, yields gently to pressure ; besides being a *constant* counter force to the muscles, it overcomes the tendency to spasm and irregular action, it acts beautifully as a lac, not causing chafing or any kind of abrasion ; a piece of chamois leather or a good fold of soft linen may be laid between the rubber and the skin, which can be changed if accidentally soiled ; the front horn of the half circle is prominent, so as to stand a couple of inches clear of the level of the pubes, and allow the connecting band to the upper end of the outer splint to pass free of the groin, and avoid any pressure on that tender region, or on the saphena vein, a point of no mean importance, and often practically one of great difficulty to arrange. This inner splint will extend from the perineum to four or five inches below the foot, and is a hand-breadth wide for ordinary subject, varying in moderate proportions according to size (Fig. 2). The outer splint is of the same breadth, and extends from about the level of the umbilicus to four or five inches below the foot. The upper end is cut with a horn in front projecting, so as to correspond with that of the inner splint, and through a hole in this, the anterior connecting band of the inner splint is attached, another hole behind allowing the posterior connecting band to be transmitted (these bands are best made of light leather, as they do not yield too much) : these are then tied together as the ordinary lac is ; both inner and outer splints (Fig. 3) are composed of two parts, one sliding inside the other, furnished with a rack on the upper received edge, into which fits a pin with a chisel point, which drops into the rack as the splint is being used for extension, which is accomplished by a simple arrangement of a miniature windlass (as shown in the illustration, Fig. 3). The rotating stem receives the cord as it is wound either by a fixed handle or by a key (detachable for refractory patients,) and the pin being raised by each tooth of the rack as it passes, drops down, and fixes the splint at any desired length ; thus each splint is a special apparatus, being furnished with two straps to the lower segment of each, the inner splint acting *directly* against ramus of pubes and ischium by the elastic, and therefore non-irritating force of the india-rubber band ; and the outer splint acting indirectly by drawing on the same medium as in the ordinary lac, without the disadvantage of pressure on the groin or constriction of any of the parts, as the projecting horns of each splint carry the connecting bands clear. Again, as each splint is capable of being elongated or wound up *independently* by the rack and windlass arrangement, the nicest adjustment possible can be made, and an equable distribution of the extending force arrived at. I also apply a simple splint behind (Fig. 4), shaped slightly to correspond to the fold of nates and tuber ischii at the

1 Hamilton on Fractures and Dislocations. Amer. Edit., 1863.
2 System of Surgery, p. 625.
3 Hamilton on Fractures and Dislocations, p. 406.

upper end, and becoming very broad below, so as to be, in fact, a separate mattrass for the limb, and prevent any possible change of position. The edges of the two side splints do *not include* this posterior splint, but rest *on it*. This posterior splint again is furnished with slits, as will be seen in the illustration, pretty close together, which transmit tapes or straps, and which embrace the side splints. By having the slits pretty close together the hinder edges of the side splints will be more closely brought together than the front when the straps are tightened, and the apparatus will thus lie neatly and pleasantly together. These slits can transmit the tapes or straps, which would retain an anterior short splint, if circumstances required its use. In hospital practice specially, this posterior splint or platform is desirable, as it acts as a mattrass to the limb, the straw beds are available, and their inequalities cause no obstruction to treatment, as is often the case otherwise, and in using the ordinary long splint. The steps of my arrangement are thus carried out; if the patient be very hairy, a razor may be passed over the sides of the limb. The straps of good fresh adhesive plaster are laid on as directed, the ankle being lightly surrounded with wool or wadding. A many-tailed bandage is arranged on the posterior splint, furnished with its pad or folded sheet, a slight padding of wool or wadding being placed under the region for the popliteal space and ham, and also a padding corresponding to the tendo-achillis. This gives great comfort afterwards to the limb when in the extended position, and should not be omitted. The limb is now placed in situ, extension made to gain fair apposition, which can be improved once it is arranged in the apparatus. The many-tailed bandage is now applied with reasonable firmness along the entire limb, the tapes are brought through on each side and tied, the lower tapes being crossed below the foot, that attached on outer side being brought through the inner splint, and *vice versa*; the inner splint is now neatly adjusted to rami of pubis and ischium, the rubber should bear more on the ischium than the pubis, as pressure there is most endurable, and care must be taken to interpose a good fold of wool or old linen between the rubber and the skin to prevent the possibility of fraying or irritation, and the connecting bands to the outer splint attached, the encircling straps are now buckled, and the windlass arrangement put into play to attain any degree of extension required, and proportioned to the amount of muscular excitability shown. The advantages of this adjustment, as compared with those ordinarily in use, are various; for, after some days the patient may be allowed freedom in moving the body, and be supported in bed in the semi-erect position, the arrangement of the splint allowing of this, and the projecting horns keeping the connecting bands from being interfered with by the raised position of the body. Of course, it is not practicable to allow this change of posture when the long splint is used, and the illustration (Fig. 3), taken from a boy under my care in hospital, shows the facility and satisfaction with which this position can be arranged; the comfort and advantage to the patient it is needless to refer to, specially in the young or those far advanced in life.

Again, when the bandages require readjustment from any cause, there is no necessity for disturbing the parts or hazarding disruption of the uniting tissue, or for raising the limb in its fragile state in order to uncoil the bandages or apply them afresh, involving the necessity of entrusting the limb in this position to an assistant, who, however careful, and directed by the most cautious and zealous surgeon, may destroy the position of the fragments, and allow shortening or disruption to take place. I cannot quote a more apt illustration of this than is given in a report by Mr. Butcher, who, with his usual exactness, remarks ("Operative and Conservative Surgery," p. 489), referring to a case of fracture of femur—"On removing the splint to-day for re-adjustment, the assistant unintentionally relaxed the traction at the ankle, and the full amount of shortening was reproduced as on admission." Now, this accident could not occur with the method I have described, all that is required being to loose the encircling straps, and separate the splints, and, if necessary, the outer splint may be loosened at the top and more room allowed. There is no necessity, once the splints are applied, ever to remove them during the treatment, as the bandages, &c., can be readjusted without disturbing the parts concerned.

In the case of a compound fracture or of a wound on either the inside or the outside of the thigh this method is particularly useful and its advantages are well seen in the case of ununited fracture referred to below, where an incision, some six or seven inches long, had to be made on the outside. Here, if the usual long outside splint was used, it would not have been possible to dress the wound without the disturbance of parts it was highly necessary to keep at rest, and a bracket of sufficient size in the splint would have been inconveniently large. In the treatment of the case the outside splint was, when required, *taken off altogether*, the parts cleansed and dressed, and yet no displacement could take place, as the inner splint was just as efficient as the outer one had been for the purposes of extension.

Should there be a wound or injury on the inner side of the limb, the inner splint can be furnished near the upper end with a hinge, opening towards opposite side, and thus, without disturbance of the india-rubber acting as a lac to the outer splint, the inner splint may be drawn out from the limb and the injured parts attended to.

The advantage of having the extending force so arranged that it is constant, and not likely to vary, when any change is required to be made in the dressing, as well as the general applicability of the splint, is well shown in the following case of a patient under the care of Mr. O'Grady :—

CASE OF TROCHANTERIC FRACTURE OF THE THIGH IN A PATIENT SUBJECT TO FREQUENT EPILEPTIC SEIZURES—UNUNITED. OPERATED ON BY MR. O'GRADY.

M. K., a strong girl, aged 25, came under Mr. O'Grady's care on January 3, 1867, suffering from an ununited fracture of the left thigh through the trochanter major. The limb was everted and shortened to the extent of five inches, with much deformity, but the normal length was capable of being restored by extension. An enormous amount of callus had formed around. A long outer splint was applied, and as she suffered numerous epileptic fits, bromide of potassium was administered till very large doses were reached.

On January 14th friction was used with the ununited ends, and the limb was put up in plaster bandages.

At the end of February the plaster was taken off and the limb examined. No union had taken place. Vigorous friction of the ends was used. A long splint from the axilla to below the foot was applied, another on the inside of the thigh, and another small one in front. The limb is now three inches shorter, with neither in or eversion; a mercurial course was also fully tried.

On the 19th May she went home, the parts being locally guarded from injury.

On June 24th she was re-admitted, as the limb was useless. It was now more atrophied, and shortened from four and a-half to five inches, but easily restored to the normal length by manipulation. The limb was placed in a Bevan's splint.

August 26th.—There being no prospect of union taking place, Mr. O'Grady determined on using more vigorous operative interference by cutting down on the ends, and passing drilled points into the extremities of the fracture. An incision seven inches long was made, and with some difficulty, from the depth and density of the parts, four drilled points were introduced to the bone, and left there. The wound was filled with a pledget of oiled lint. The apparatus I have described was applied, and I was happy to have had the opportunity of testing it in a case of the kind, where its utility would be fully tried. The limb was now at proper length arranged in the splints. In

about one hour and a-half after the operation she suffered a severe epileptic fit, but from the compactness and power of the apparatus there was no disturbance of the parts. The day after she suffered two violent fits, and has since had numerous epileptic seizures eight to ten per week. During these, necessarily the limb is subject to considerable violence.

On January 5th, on examination, there is found about one inch of shortening. It is not considered judicious to examine too freely; but the outer splint is now removed, and the inner alone applied, which answered perfectly. The case is still under treatment, and the report shows that the splint acted efficiently and agreeably in the treatment of such a case, complicated with a free external wound on the outside, and with frequent and severe epileptic seizures.

FRACTURED FEMUR IN A BOY AGED TWELVE YEARS.

J. G., a boy aged twelve, was admitted to Mercer's Hospital on the 27th November, 1867, the left knee-joint had been partially ankylosed, and the limb slightly shortened from previous disease. He says, that coming along the quay, where there is a high kerb-stone, he slipped and fell on the thigh. He was brought immediately to hospital, where he was found to have oblique fracture at the juncture of the middle and upper third of the thigh. There was shortening to the extent of one and a-half inches, and a good deal of deformity.

The apparatus not being immediately available at the time, a long splint was applied. On the next day I put on the apparatus above described; it answered admirably, the many-tailed bandage giving pleasant support, the india-rubber band acting as the counter-extending point, and the broad posterior splint keeping the limb steady. The apparatus was not removed during the entire treatment, but it was opened twice, and the bandages readjusted, using more agreeable pressure. The patient never made a complaint from over pressure or irritation of the skin. He was discharged cured on January 1, 1868, a starch bandage being applied to the limb, which was perfect.

The illustration (Fig. 3) is taken from this case, as well shown in the semi-erect position. It will be seen that there is no relaxation of the extending or counter-extending force, and there is no impediment to the change of posture.

FRACTURED THIGH IN A BOY AGED TWO YEARS.

The subject of this case, a fine little boy of two years of age, was thrown against the kerb-stone in the street, causing a transverse fracture of the middle of the right thigh. He was brought to hospital shortly after the occurrence of the accident on August 22nd, 1867. I had a small apparatus made and applied to the limb, the hinder splint being here very convenient, owing to the age and restlessness of the patient. The apparatus was not disturbed during the entire treatment, and the little patient had the enjoyment of the semi-recumbent position. It required twice a turn of the small windlass arrangement owing to the relaxation of the tapes. The patient was discharged on September 22nd, the limb being perfect.

OBLIQUE FRACTURE OF THE THIGH IN A CHILD UNDER TWO YEARS OF AGE.

J. M., a healthy boy, fell off a box, and received a fracture of the right thigh. He was immediately brought to the hospital, and presented, considering his age, a remarkable amount of deformity. I applied the apparatus above described with great comfort to the little patient, and the condition of the limb was all that could be desired; the child could sit up during the entire treatment. He is now about being discharged cured, and the limb perfect.

In these instances, occurring within a few months, I have found the apparatus to answer most satisfactorily, giving the advantage of being able to have the body raised, relieve the tedium of treatment, and without risk of causing irritation of the ankle, heel, or foot.

In cases of hip-joint disease this apparatus is very convenient and even when there is ulceration of the surface or any difficulty in applying an outside long splint, I use the inner one alone, and find it most efficacious and applicable. The india-rubber tension overcoming any tendency to spasm, the patient after the application finds relief, owing to the steadying influence exerted on the limb, the inner splint alone or in combination with the hinder splint, can be used. In disease of the knee joint, likewise, it forms a most useful box, and by gentle traction relieves the irritation caused by pressure. Not the least recommendation I hope, also, is the cheapness of the apparatus; there is nothing of an elaborate construction, nor can it easily get out of order, and if so any one can rearrange it.

These advantages I have found so practically useful, that I trust I have succeeded in adding yet another apparatus, which will at least take its place amongst the many which have been devised for the treatment of these very important injuries and diseased conditions, and commend itself by its utility, efficiency, and practicability.

DR. ROBERT McDONNELL'S LECTURES ON SYPHILIS.

QUESTION OF INCUBATION OF THE PRIMARY LESION OF SYPHILIS.

By CHARLES R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.

THE period of incubation of the primary or local lesion in syphilis is a very difficult ascertainment, and, moreover, it seems by no means to be invariable in its length. The admirably observed case cited by Dr. Robert McDonnell in THE MEDICAL PRESS AND CIRCULAR of Jan. 29th, 1868, gives the period as thirty-one days. Professor Böeck has told me he has remarked that when inoculation is made from an indurated *sore*, there is little or no incubation in general; whilst, when a person is infected from a secondary symptom, the period of incubation is often rather long. Baerensprung puts it down at twenty-eight days, and in the cases, now amounting to a considerable number, where blood and other secretions of syphilitic persons were inoculated on healthy persons, the period of incubation of the primary lesion was found to be about a month. The following case of well-marked incubation period was seen by me at the Farringdon Dispensary, Holborn, on the 16th March, 1865. A modest-looking young girl, aged nineteen, came with a remarkably hard non-suppurating sore on her right lower lip. Submaxillary glands were hard. Diagnosis indurated chancre. The girl was modest and well-bred, and I was at a loss to account for this fact. On inquiry it appeared that she was engaged in marriage to a man, and that one evening, at the beginning of February, he had, on bidding her good-bye, bitten her lip playfully in kissing her. She remembered the time well, because the lip was painful after it. Three weeks afterwards she felt a lump in the lip, which gradually enlarged until it became the size of a hazel nut, when she came to consult me. This gave an incubation period of upwards of three weeks, or twenty-one days. I may add that the girl soon had roseola and periostitis of the tibia and slight alopecia, with mucous tubercles, all of which gradually, though slowly, got well under doses of pot. chlor., and, in about nine months, being free from stains, she married, and became pregnant, after which I lost sight of her.

THE STARCH BANDAGE IN FRACTURES OF BONES OF EXTREMITIES: CASES AND OBSERVATIONS.

By P. C. LITTLE, F.R.C.S.I., &c.

To the uninitiated, the number and variety of surgical appliances for the treatment of fractures must seem surprising and unnecessary. The task of comprehending the

special objects, not to mention the practical applications, of such countless instruments, has often cooled the ardour of the neophytes in surgery, as all can testify. And still these implements are daily becoming more numerous, and more complicated. The so-called improvements made in them, from the time of Hippocrates to the present, may have been useful in the development of mechanical art; but how much have they advanced the science and practice of our profession? Certainly not much in the view of the fact, that, the true conservatives of the healing art—those who adhere to its principles, evince a growing disposition to return to the treatment of fractures adopted by the early fathers of surgery. Having had, for some years, frequent opportunities for testing the advantages of the starch bandage, I am induced to record briefly, a few cases recently treated with it, and the general result of its use, which, I hope, may prove of interest to your many learned readers.

CASE I.—FRACTURE OF INTERNAL MALLEOLUS.

Jan. 6th.—I was called in attendance upon E. K., æt. 41, a master mariner just returned from a long voyage, who had met with an accident on the Atlantic three weeks ago. During a tempest, a loose spar on deck struck him violently on the right leg, about three inches above the external ankle, depriving him almost entirely of the use of the limb, and causing much pain. His sufferings were increased, by his having had, through stress of weather, to remain pretty constantly on deck since the occurrence.

The injured limb is blue and much swollen, particularly about the ankle; but it preserves the form of the sound one, excepting in its being an inch and a-half shorter, in consequence of an old fracture through upper third of thigh. The skin feels tense and hot over the seat of injury. I could discover no crepitus, or solution of continuity in either the fibula or tibia. There was much tenderness on pressure at the internal malleolus. The ginglymoid motion of the joint was normal. Its lateral motion, especially abduction, was unusually free, which led me to suspect fracture of the internal malleolus. There was no dislocation, the bony constituents of the joint preserving their proper relative relations.

I advised six leeches to be applied over the inner ankle; afterwards a warm poultice of bran and linseed-meal; the limb to be retained in the horizontal position on a back-splint with foot-piece, which I extemporized, and retained in its place by a few turns of a bandage below the knee and over the instep. As the bowels were confined, I prescribed to be taken at bed-time a bolus containing: pul. jal. co. gr. xx., with cal. gr. x.; nourishing diet, no stimulants.

Next day he was a good deal easier. There was still much heat about the ankle, but the pain and swelling had so much diminished that I had no difficulty in making a satisfactory examination of the injured parts. I then discovered a transverse fracture of the internal malleolus, immediately at its junction with the shaft of the tibia. There was no displacement of the fragments, unless in abduction of the foot, when a distinct interval was created at the seat of fracture. I recommended the application of a cold evaporating lotion: (Liq. ammon. acet. ℥iij., sp. vin. rect. ℥ij., aquæ ex font. ℥xij.), which allayed the heat and swelling in two days.

I then coated the limb, from the toes to above the knee-joint, with cotton wadding, laying it on pretty heavily over the joints and shin to obviate pressure; after which I adjusted on either side of the ankle, broad slips of pasteboard, well softened in thin starch, and over all applied evenly, and with considerable pressure, the starch-bandage. I began from above the toes, and made several times the figure of 8 across the ankle for additional support. Over this I ran a dry roller, and lashed all to the extemporised splint to harden. In less than two days the bandage had become consolidated, the splint was laid aside, and I allowed the patient to get up, and occasionally move about the house, supporting himself with a crutch, and the affected limb with a wide calico sling around the neck and sole of the foot. I did not find it necessary to remove the starch apparatus until about a fortnight after this, when he had fully regained the use of the limb, and resumed his active occupation.

CASE II.—FRACTURE OF TIBIA AND FIBULA.

Jan. 8th.—J. R., aged 47, a very able and healthy man, though rather intemperate, while returning to his residence in the suburbs the night before last, stumbled against the gutter embankment, fell heavily, and fractured his right leg. Being unable to walk, he was carried home in much suffering and put to bed. The treatment followed, up to my seeing him, was hot stupes locally, and stimulants internally. The right leg was greatly enlarged, bright red, and shining; tender to the touch, especially around the ankle, which was brawny-looking. The foot was slightly everted; the outline of the fibula was interrupted by a small depression about two inches above the external malleolus; the internal malleolus seemed more prominent than usual. The motions of the joint were uncommonly free, abduction remarkably so, apparently from relaxation of the internal ligament. I did not persevere in the examination, as it was intolerable to the patient. Therefore, directing my attention to the relief of the more urgent symptoms, I extended the limb on a hair pillow, using the end board of the bed as a support for the foot, and ordered the immediate free leeching of the ankle, the administration of an active saline aperient, low diet, and perfect rest of the limb. Under this treatment, the high inflammation had been so far subdued by next day that I was enabled to fully investigate the case. I then found crepitus with lateral motion of the joint, and an oblique fracture of the fibula about two inches from its lower extremity, and fracture also of a fragment of the internal malleolus, with stretching of the ligament attached. I prescribed the cold evaporating lotion, as in Case 1. In two days afterwards I applied the starch apparatus, and with the usual success. The patient was able to go out on business, with the support of a stick, in three weeks, and can now walk without any such help, as well as before the accident.

A short time previous to the occurrence of those fractures of the lower extremity, I had under my care two cases of a similar character, of which I only preserved the following short notes:—

CASE III.—FRACTURE OF TIBIA AND FIBULA.

J. N., aged 60, with right tibia and fibula broken two inches above ankle, from a fall off a car. I had twice attended him previously for dislocations of right ankle-joint.

CASE IV.—FRACTURE OF FIBULA.

J. S., aged 42, right fibula fractured three inches above external malleolus, the smaller fragment overlapping the larger; luxation outwards of foot; and stretching of internal lateral ligament, resulting from a slip off a curb-stone.

In both cases rapid and complete recoveries followed the use of the starch apparatus.

CASE V.—FRACTURE OF RADIUS.

Oct. 11th.—I was called in haste to Mrs. M., æt. 24, who had fallen "heels over head" down stairs, her right wrist coming under her three times. On my arrival, finding that she had become faint, I ordered her some wine, which soon revived her. She complained of intense pain in the fore-arm; inability to move it; and necessity of supporting it with the left hand. She was suffering from severe shock, and afraid to allow anyone to touch the disabled limb. After a little time, I succeeded in examining it. The hand was everted, the palm looking downwards, and outwards. The wrist was tumid, blue, and very painful in handling. There was a swelling from the base of the metacarpal bone of the thumb, in the line of the radius, for about two and a half inches, where it ended in a sharp

prominence, with a depression behind, that is, above it. On fixing the radius, and rotating at the same time the hand, crepitation was distinctly heard, and solution of continuity of the bone felt.

I placed the hand on a thin piece of board, and slung it to the neck; ordered the cold evaporating lotion to be constantly applied to the wrist, and the patient to remain quiet.

Next day I put up the limb in the starch bandage in the usual manner, and after three weeks I removed the appliance, and substituted a dry roller. The patient soon recovered the use of her limb without deformity.

The causes of fracture of the limbs are manifold, and the circumstances which modify their effects are even more numerous. In accidents, such as the above, fracture generally occurs from a force acting indirectly on the bone, owing to the economic and physiological laws of our structure. When, however, as in Case 1, a great force strikes directly a slender bone like the fibula, destruction of its continuity is anticipated. Why was not such the effect in the case referred to? A smart stroke of a poker across the fibula has been known to break it, without injuring the tibia. Here, a large spar rolls with great velocity against the fibula, and only fractures the tibia. True, the fibula is more elastic, not so superficial, better covered with muscles, less useful in locomotion than the tibia. But, a better explanation appears to be in the mechanical laws of concentration and diffusion of force. The impulse against the fibula of so broad a substance as the spar, was diffused towards the extremities of that bone, while the same force was sufficiently concentrated on the opposite side of the limb to fracture the cancellous lower extremity of the tibia. Professor Smith, of this city, considers simple disjunction of the inferior epiphysis of the tibia to be of very rare occurrence. This is an example of that unusual pathological condition. These cases exemplify the greater frequency of fracture of limbs on the right side of the body.

The treatment of fractures by the starch bandage, in my experience, has been most satisfactory. Its simplicity, inexpensiveness, and readiness of application; its obviating the dangers of inflammation of the lungs, bed-sores, and general impairment of health; its allowing the patient to move about soon and attend to business; or, if an hospital patient, its permitting of his leaving in a short time, to give place for more urgent demands on the charity; and, above all, its perfect adaptation to the end we should steadily keep in view,—all recommend it, I think, before any other appliance for the management of fractures of extremities. The principle of our treatment of fractures is, to restore to their original positions, and so retain the divided bones. This, the starch bandage achieves, by efficiently controlling muscular action, and preserving co-aptation of the fragments. The wet starch bandage is so powerful as an evaporating medium, that it is particularly useful in subduing slight inflammatory conditions which attend fractures. I confess, I have been slow to apply it until high inflammation had been reduced by other means, notwithstanding the contrary practice of Mr. Erichsen, in University College Hospital.

There is no doubt plaster of Paris, so strongly advocated by Dr. Gurlt, of Berlin, is a more cleanly, and more quickly solidifying material than starch, but it is not so cooling, nor so easily obtained as the latter, which is found everywhere. For a considerable period, the practice of putting up fractures, with simple adhesive plaster, has been followed with great success in the United States, and astonished Mr. Spencer Wells on his recent holiday trip to that world of invention. Mr. Wells speaks highly of that plan of treatment, but, with good, reason, fears that sufficient immobility of the bones cannot be obtained with that material. This, I should say, is particularly to be apprehended in fractures of the femur and humerus.

It appears that the starch bandage was first used in this city by Mr. Kirby, eighteen years ago. It has since been sparingly resorted to, although strongly recommended in our journals, by such able surgeons as Mr. Fleming, and Mr. Maurice Collis. It is probable, however, that, with the present advance in professional knowledge, this valuable appliance will soon be very widely adopted, as being the most rational and uncomplicated means of treating fractures. When that period arrives, we shall be able, in this kingdom, to dispose of such an accumulation of implements of wood, straw, tin, iron, brass, leather, gutta-percha, &c., now employed for fractures, as would constitute an immense, if not a becoming monument to the memorable advocate of the starch bandage, the Baron Seutin, of Brussels.

Hospital Reports.

SURGICAL RECORDS.

By WILLIAM STOKES, Jun.,
SURGEON TO THE MEATH HOSPITAL AND RICHMOND SURGICAL HOSPITAL.

STRICTURE OF THE URETHRA.

As this subject is one which unquestionably is of such eminently practical importance, I trust a brief record of a few cases of this disease, which, with one exception, I treated by internal urothrotomy in the manner first suggested and practised by M. Maisonneuve, may not be considered devoid of interest.

CASE I.—STRICTURE OF URETHRA OF TWELVE YEARS DURATION—INTERNAL UROTHROTOMY.

W. B., æt. 42, was admitted into the Meath Hospital on October 20, 1865. He stated that he had suffered from urethral stricture for upwards of twelve years, and ascribed the disease to repeated attacks of gonorrhœa, which he had had during his youth. For many years previous to his admission into hospital, he was in the habit of having instruments passed from time to time. Of late, considerable difficulty was experienced in doing so, and when he came under my observation in the Meath Hospital, No. 3 catheter was the largest instrument that could be introduced, and that by very delicate manipulation. Having had no reason to change my opinion as regards the great value of M. Maisonneuve's method of treating urethral stricture, I recommended it to the patient, and as he willingly complied, the operation was performed without any difficulty whatever on October 28th. I may mention that in this case, the stricture was divided on the under surface of the urethra. After the operation, a large conical-shaped gum-elastic catheter was introduced without any difficulty, and kept in the bladder for forty-eight hours. During convalescence, the patient had no rigor or other evidence of constitutional disturbance. On November 5th the patient left the hospital able to pass water in a full and uninterrupted stream.

CASE II.—COMPLICATED DOUBLE STRICTURE OF URETHRA OF FOURTEEN YEARS' DURATION: SCROTAL FISTULA COMMUNICATING WITH URETHRA: INTERNAL UROTHROTOMY.

W. K., æt. 52, formerly a soldier in the Bengal Army of the East India Company, was admitted into the Richmond Hospital under my care on January 28th. The patient states that fourteen years ago he contracted gonorrhœa in India, and was treated solely by injections of sulphate of copper, since which he has suffered more or less from difficulty in passing water. About eight months ago the patient states an abscess formed in the mesian line of the scrotum at its most depending portion, and since this opened the urine has made its way through it, forming a urinary scrotal fistula. On examining the urethra, I found, situated in the anterior portion of the canal about three inches from its orifice, a hard callous stricture through which, although I made repeated attempts, I could not succeed in introducing the smallest gum-elastic catheter. As all attempts to heal the fistula would necessarily prove unavailing unless the stricture were in the first instance

successfully treated, I determined that should I be able to introduce one of the filiform bougies of Maisonneuve to divide the stricture by internal urothrotomy. I fortunately succeeded in passing the bougie, and in doing so, determined the existence of a second stricture in the usual situation. The patient did not lose more than a few drops of blood during or after the operation, and after this was completed, I succeeded in introducing without difficulty a No. 9 conical gum-elastic catheter, and drew off a large quantity of urine. Since the operation no unfavourable symptom has supervened.

CASE III.—STRICTURE OF URETHRA OF SIXTEEN YEARS DURATION, COMPLICATED WITH PERINEAL FISTULA: PERINEAL SECTION.

M. H., æt. 62, was admitted into the Meath Hospital on the 16th of last December, suffering from urethral stricture, and perineal fistula, the latter complication having existed for upwards of six years. For some time after his admission, I made numerous but unavailing attempts to introduce an instrument into the bladder. Neither the filiform bougie of Maisonneuve, or the catgut director of Dr. Hutton's railway catheter, or the finest of the self-dilating sea-weed bougies, could possibly be introduced. On consultation with my colleagues, I determined to perform a modification of Professor Syme's operation of perineal section. According, on the 18th of January, the patient was brought into the operating theatre, and placed in the lithotomy position. A large silver catheter was introduced into the urethra down to the seat of the stricture, and held firmly in that situation by my colleague, Mr. Wharton. I commenced the operation by making an incision with a long straight bistoury, along the raphe of the perineum, terminating at a point about three-quarters of an inch in front of the anus. The soft parts were divided freely down to the extremity of the silver instrument, which rested against the stricture. I then introduced, and with the nail of my left index-finger felt distinctly the contraction beyond the point of the large silver catheter. The stricture I then succeeded in dividing, with the point of the straight bistoury, which I used, in the first instance, for making the external incision. In doing this, which required some delicate manipulation, I took especial care to keep the handle of the bistoury well depressed. With greater facility than I had at all anticipated, I arrived at the dilated portion of the canal beyond the seat of the stricture. At this juncture, Mr. Porter handed me a full-sized gum-elastic catheter, without any stylet, which I fortunately succeeded in introducing into the bladder through the wound. The next difficulty I had to encounter was to bring the fore-part of the catheter through the anterior portion of the urethra. For accomplishing this, I had recourse to a manœuvre which Mr. Porter's ingenuity at once suggested, and which was attended with complete success, and I can recommend it most strongly to all surgeons who may have to deal with similar cases. It consists in removing the ivory head of the catheter which was introduced through the wound, into the bladder, in the first instance; secondly, in introducing through the orifice and anterior portion of the canal a conical-shaped bougie, the extremity of which, when brought down to the wound, was fixed firmly into the open end of the gum-elastic catheter. The bougie is then slowly withdrawn through the anterior portion of the urethra, bringing along with it the gum-elastic catheter. The two instruments are then separated, and the catheter fixed in the urethra in the ordinary manner. Since this operation was performed, the case has progressed most favourably. The wound in the perineum is gradually closing; little or no urine escaping through it, and large-sized catheters are frequently introduced with the greatest facility into the bladder.

CASE IV.—STRICTURE OF THE URETHRA OF TWO YEARS DURATION.—INTERNAL UROTHROTOMY.

C. M., æt. 34, was admitted into the Meath Hospital under my care on the 4th of last October, suffering from stricture of the urethra, which he stated he had had for the last two years. The stricture was situated in the membranous portion of the urethra, and the disease the patient attributed to an attack of gonorrhœa which he had three years previously, and which he had much neglected. As this was in every respect a perfectly uncomplicated case, but so extremely close a stricture as not to permit of gradual dilatation by the ordinary gum-elastic catheters (which, though the slowest, I believe to be the safest mode of dealing with the great majority of such cases), I determined to treat it by internal urothrotomy, and accordingly performed the operation, and without any difficulty, on the 8th of last October. After the operation I introduced a No. 10 catheter. No rigor or any evidence of constitutional disturbance supervened during the patient's convalescence, and when he left the hospital so large an instrument as No. 12 could be introduced without any difficulty whatsoever.

CASE V.—STRICTURE OF THE URETHRA OF FIFTEEN YEARS' DURATION—INTERNAL UROTHROTOMY.

T. N., æt. 54, was admitted into the Meath Hospital under my care on the 6th of last December. The case presented all the symptoms, local as well as constitutional, of urethral stricture. The stream of urine was extremely small, and the desire for micturition so frequent as to make me suspect the case was complicated with some prostatic irritation. The stricture was an extremely close one, so much so that it was not until I made frequent attempts that I at last succeeded in introducing a No. 2 catheter. Any larger instrument than this I failed in getting in. Accordingly, I determined to treat the case by internal urothrotomy, which operation I performed on the 9th of December, and immediately after I introduced a No. 10 catheter, which I fixed in the bladder in the ordinary manner. Nothing untoward occurred during the patient's convalescence, and on the day he left hospital (December 17) No. 11 gum-elastic catheter was passed without the slightest difficulty. The functions of the bladder, also, were completely restored, the frequent and urgent desire for micturition, which he suffered from previous to the operation, having completely subsided.

I might adduce the particulars of other cases of stricture which I have treated successfully in the same manner; but for the present I think the above cases are sufficient to show the great practical value of internal urothrotomy in the treatment of strictures of the urethra.

PAUPERISM.—The Poor-law Board have issued another half-yearly return showing the state of pauperism in England and Wales on July 1, 1867. The number of persons in receipt of relief from the rates is given as 926,303, but returns relating to places not under Boards of Guardians, comprising nearly 1 per cent. of the population, are not forthcoming. The return shows an increase of 5 per cent. over the number on July 1, 1866; and there is an increase of 6·7 per cent in the number of adult able-bodied paupers, which is 144,665. The pauperism of July 1, 1867, was constituted thus—Men, 187,239; women, 401,557; children under 16, 332,043; and vagrants, 5248. The adult paupers 16 years old and upwards, are thus classified:—Able-bodied, 34,102 men and 110,563 women; not able-bodied, 135,388 men and 268,038 women; insane, 17,729 men and 22,956 women. There were also 808 children insane, making the whole number of insane paupers 41,513, an increase of 2083 over the number a year before. The increase of pauperism shown by this return is far greater in the metropolis than in any other division of the kingdom. Instead of being 5 per cent., it amounted in the metropolis to 18·7 per cent.—7·8 per cent. in that part which is in Kent, 11·8 per cent. in the part in Surrey, and no less than 22·4 per cent. in that part which is in Middlesex. The increase is very marked in Poplar and other districts at the East-end of London. The increase in adult able-bodied paupers in the metropolis, instead of being 6·7 per cent., was 13 per cent. The total number of paupers relieved in the metropolis on July 1 was 97,981 in 1865, 106,202 in 1866, 126,094 in 1786.

REPORT TO THE REGISTRAR-GENERAL ON THE METROPOLITAN WATER SUPPLY.

By Dr. E. FRANKLAND, F.R.S.

ANALYSIS OF THE METROPOLITAN WATERS FOR JANUARY, 1868.

1 Companies.	2 Date and Place of Collection.	3 Temperature[1] in centigrade degrees.	4 Total solid impurity in 100,000 parts.	5 Organic Carbon.	6 Organic Nitrogen.	7 Nitrogen as Nitrates and Nitrites.	8 Ammonia.	9 Total Combined Nitrogen.	10 Previous Sewage Contamination (Estimated.)	11 Total Hardness.

For the purpose of comparison, I append also the results yielded by Loch Katrine water, as supplied to Glasgow, and by waters supplied to the towns of Lancaster, Manchester, Leicester, and Preston, when submitted to the same analytical processes. The numbers in columns 4, 5, 6, 7, 8, 9, 10, and 11 all relate to 100,000 parts of the waters. The table is to be read thus: the Chelsea Company's water collected on 21st January, at the Horse Guards cab-rank had a temperature of 7·2 C., it contained 29·2 lbs. of solid impurity; the organic matter constituting a portion of this impurity contained ·353 lb. of carbon and ·058 lb. nitrogen. This solid impurity also contained ·339 lb. of nitrogen in the form of nitrates and nitrites, besides ·001 lb. of ammonia, whilst the total amount of *combined* nitrogen in every form was ·339 lb. The above quantity of water supplied by the Chelsea Company had been, after its descent to the earth as rain, contaminated with sewage or manure matter equivalent to 380 lbs. of average filtered London sewage.

By gradual oxidation, partly in the pores of the soil, partly in the Thames and its tributaries, and partly in the reservoirs, filters, and conduits of the Company, this sewage contamination had been converted into comparatively innocuous inorganic compounds before its delivery to consumers. Finally, 100,000 lbs. of the Chelsea Company's water contained 15·4 lbs. of carbonate of lime, or an equivalent quantity of other soap-destroying ingredients.

The waters delivered in London during the latter part of January by the Chelsea, and especially by the Southwark and Lambeth Companies were in such a muddy condition as to render them totally unfit for domestic use. The Thames has overflowed its banks above the point at which the water supply is withdrawn, and by washing the surfaces of cultivated fields and mingling with the contents of stagnant ditches and ponds has become contaminated to an intolerable degree. Those companies which, like the West Middlesex and Grand Junction, possess ample and efficient filtering apparatus, were enabled so far to cope with the difficulty as to send out their supply free from suspended matters. A week later, however, than the date when the samples were collected, the water of the Grand Junction Company had also become turbid, but much less so than that delivered by the Southwark and Lambeth Companies. It will be seen from a reference to the analytical Tables that the Thames was comtaminated at the time the samples were taken with double the usual proportion of organic matter. Besides dissolving the soluble manure matters from cultivated fields, the recent heavy rains flushed the sewers of Oxford, Windsor, &c., dislodging great quantities of putrescent animal matters and sweeping them into the Thames; hence the large proportion of organic carbon and nitrogen, and the great previous sewage contamination in the waters of those companies which derive their supply from that river. The West Middlesex Company's water, though well filtered and perfectly transparent, had been thus contaminated to an extent which would be produced by the admixture of one-third of a gallon of average filtered London sewage with each ten gallons of the water. The River Lea also exhibits a very high previous sewage contamination, but at the time when the New River and East London Companies samples were collected it had not been affected like the Thames, for, although the East London water was full of suspended brown particles, the analyses of these waters show that the organic carbon and nitrogen are remarkably low for the season. The Kent Company's water was slightly turbid from yellow particles.

ROYAL COLLEGE OF CHEMISTRY,
London, Jan. 31, 1868.

1 The average mean temperature of the Thames during the three days, January 20, 21, and 22, was 5·7° centigrade; the average during the week ending January 18th was 3·3° centigrade.

THE CLAIMS OF THE ST. ANDREWS MEDICAL GRADUATES TO THE FRANCHISE.

THE following memorandum, dated Feb. 12th, concerning the claims of the St. Andrews Medical Graduates to the franchise, has been submitted for the consideration of the Right Hon. the Chancellor of the Exchequer by the Council of the St. Andrews Medical Graduates' Association:—

"The regulations regarding the conferring of medical degrees in the University of St. Andrews adopted in 1826, continued in force (with only slight alterations in 1833) until 1863, when they were altered by the Scotch University Commissioners.

"The degree of doctor of medicine of St. Andrews is recognised by 'The General Council of Medical Education and Registration of the United Kingdom,' and entitles its holder to the same status, and confers on him the same legal rights as the degree of M.D. of any other university.

"The regulations empowered the university to confer the degree of M.D. on any legally-qualified practitioner of good character after passing the requisite examination. In 1863 the Scotch University Commissioners continued this power but restricted the number of degrees granted in such manner to ten annually, and required the candidates to be upwards of forty years of age.

"The regulations in force both before and after 1863 provide a curriculum of the studies to be pursued in the university by resident students who are desirous of obtaining the degree of doctor of medicine; but as there is no recognised hospital at St. Andrews, and no means of obtaining a thorough medical education there, these regulations have been practically in abeyance.

"During the war early in this century the degree of M.D. was conferred on persons obtaining medical appointments for instant duty in the army and navy, on the certificate of eminent London physicians or surgeons, but since then no one has been admitted except after examination.

"The examination for the degree lasts three days, is partly written, partly *vivâ voce*, and is in every respect similar to that for the membership of the Royal College of Physicians of London.

"The examiners are unknown to the candidates, and a certain number of them are always distinguished graduates of other universities.

"The Scotch Reform Bill of last session provided for the admission to the general council of their university, and in consequence to a vote for its member in Parliament, of those graduates only who had attended classes during one session in the university; with the exception, in the case of St. Andrews, of those doctors of medicine who had obtained their degrees since 1863.

"By this clause, all the doctors of medicine of Edinburgh would be entitled to be placed on the general council, and to vote for the member of parliament, whilst all but 46 out of the 1350 doctors of medicine of St. Andrews would be excluded both from the general council and the franchise. The 46 voters are admitted under the proviso they have not resided at the university, and their examination has not been more stringent, but has been less in extent than that of the graduates who passed in previous years.

"The reasons which have been given for the exclusion from the franchise of their university of a large body of educated men in positions of responsibility and trust are various. It has been said—

"(1.) That the degrees have been sold. The registrar of the university writes that there is no truth in this statement.

"(2.) That the examination is poor and unsatisfactory. For some years before 1858 the rejections were in the proportion of 1 to 4 admissions. No calculation has been made since then until 1862, when 606 candidates passed; in this year the rejections were 1 in 8½. This large number of admissions is no proof of a lax examination, but furnishes strong evidence that the limitation in the number of M.D. degrees granted by the university to ten annually, and to candidates above 40 years of age, does not meet the requirements of the profession and the public. Very many do not wish to become doctors of medicine until they have been some years in practice and are able to know whether such a degree would be of advantage to them or not. Such men, and those who for various reasons—improving social position, a wish to become consultants, &c.—desired, or thought that at some future time they might need, the M.D. degree, and who under the old rules would have been distributed over many years, were in consequence of the new regulations obliged to present themselves for examination in this year, or be excluded in large numbers by the limitation to ten annually. Under these circumstances, and considering that all the candidates were at the time of their examination legally-qualified practitioners, the number of rejections (1 in 8½) is conclusive as to the validity of the examinational test. The Army and Navy Medical Boards require every candidate for employment in the services to be at the time of his application a legally-qualified man, and to undergo another examination: 32 per cent. of the candidates who are members of the Royal College of Surgeons of England, 18 per cent. of those who are doctors of medicine of Edinburgh, and only 8 per cent. of those who are doctors of medicine of St. Andrews, fail to pass. In London, 39 doctors of medicine of St. Andrews are attached to the hospitals, the medical schools, and the large infirmaries, including among them St. Bartholomew's, Guy's, St. George's, Westminster, London, Charing-cross, Bethlehem, St. Luke's, and 22 similar institutions. *In the provinces, there is hardly a large town in which a doctor of medicine of St. Andrews does not hold an important post in connection with the chief hospital.* Nineteen medical superintendents of county asylums are St. Andrews M.D.'s, as also two deputy-lieutenants, twelve justices of the peace, ten coroners and deputy-coroners, six examiners in medicine, six officers of health, three F.R.S., eleven F.R.C.P.Lond., and fifty-five F.R.C.S.Eng. The ratio of rejections and the success of the doctors of medicine of St. Andrews at the army and navy boards are proofs of the strictness of the examination, and their social and professional position is cogent evidence of public confidence and esteem.

"(3.) That the majority are Englishmen, and should not vote for a Scotch university. If the university does not refuse to admit to examination any one who is not a Scotchman and to grant him the degree of M.D., there can be no reason (in the absence of express statute to the contrary, in existence prior to the candidate's offering himself for examination) why he should be deprived of the rights and privileges which in other universities pertain to that degree. In no other university, and now not in St. Andrews, is nationality taken into account, and by the late bill no English graduate of Edinburgh was excluded from the franchise of his university.

"(4.) That the medical graduates have not resided in the university. If St. Andrews is to grant medical degrees at all, it must grant them to non-residents, for it has no hospital and no school of medicine. And even if it were in future to require residence of all its graduates, those who have already obtained their degrees should not be affected by regulations which were not in existence at the time of their examination. The doctors of medicine have complied with all the regulations of the university, and claim to be entitled to exercise every right or privilege which may be granted to any medical graduate. The University of London is in a similar position: it provides no medical school, and consequently requires no residence within its walls; but it has a representative in Parliament, and its doctors of medicine have a vote in his election.

"Should the medical graduates of St. Andrews be excluded from the franchise, the doctors of medicine of the United Kingdom would be divided into two classes, voters and non-voters, the latter being nearly all the St. Andrews men. The result would not be doubtful. The public would recognise this difference as a mark of inferior rank and knowledge; and a large number of educated men, scattered over the whole kingdom, and possessing the confidence and esteem of their neighbours, would be exposed to injurious comparison with their brethren, who, possessing no better degree, are yet voters, and would suffer a grievous injustice and a serious injury to their social and professional status; an injury which, in the army and navy, would not be confined to the individual, but would be destructive of the subordination and efficiency of the services."

Reviews.

ATLAS OF PORTRAITS OF DISEASES OF THE SKIN.

Edited by the New Sydenham Society. Seventh fasiculus.

OUR readers are so well acquainted with the portraits of this Atlas, which have been already issued, that we need not give any explanatory introduction as to their merits or peculiarities. There are three plates in this seventh fasiculus: Plate XVIII. representing a case of Molluscum Simplex, "seu fibrosum;" Plate XIX. representing a case of Lupus-Psoriasis; and Plate XX. representing a case of Porrigo Contagiosa (e Pediculis),

or Common Porrigo. In this instance the disease is depicted as occurring on the occiput of a child, and the plate is a remarkably good one, especially when closely examined through a magnifying glass. At the left hand corner are given various synonyms by which the disease is known, a very useful and most necessary kind of information at present, when the medical world is inundated with a complex cutaneous nosology, which Mr. Erasmus Wilson is striving to reduce to something like order and simplicity in his new "Journal of Cutaneous Medicine." Plate XIX. which is, perhaps, a little highly coloured, but which is otherwise perfect, has also a table of synonyms, such as we have above described. Plate XVIII. represents a case of Molluscum Simplex in an adult male; like the rest, it is quite worthy of being placed in the same scale of merit with its seventeen predecessors.

EDINBURGH MEDICAL JOURNAL. For February, 1868. No. CLII.

In the pages of this excellent serial we find reviews on Laryngoscopy, and Cholera in India, and other important questions; varied miscellaneous matter; and eight "original communications," some of which are particularly worthy of note, and all respectable. Among the contributors will be found the names of Reith, Taylor, of Nottingham; Charles Bell, Sanders, Arthur Mitchell, Grainger Stewart, and A. Christy Wilson. The first paper is a particularly good one.

THE DUBLIN QUARTERLY JOURNAL OF MEDICAL SCIENCE. February, 1868. No. LXXXIX.

We have much pleasure in calling attention to the excellent material to be found, as usual, in the pages of our respected contemporary.

There are no less than seventeen reviews of greater or lesser length; and a medical miscellany of a wide and varied character.

There are eight "original communications" on various subjects in medicine, surgery, and obstetrics; and the names of the contributors are, in most cases, quite sufficient to secure a good reading for their essays. These names are—W. Stokes, (Jun.); A. H. M'Clintock; Fleetwood Churchill, President of the Irish College of Physicians; James Cuming; Robert McDonnell, F.R.S.; John K. Maconchy; William Moore; and Lawson Tait. The "get up" of the journal is as good as usual.

NELIGAN'S MEDICINES: Their Uses and Mode of Administration. By Rawdon Macnamara, Professor of Materia Medica, Royal College of Surgeons in Ireland, &c. Including a complete Conspectus of the British Pharmacopœia, an account of New Remedies, and an Appendix of Formulæ. Seventh Edition. Dublin: Fannin & Co. 1867.

This is a very large book of Aldermanic proportions, numbering no less than 934 pages of royal 8vo., well printed on good paper, handsomely bound, and issued by its enterprising publishers in a manner, and at a price, which is most creditable to them, and to the Dublin School of Medicine.

Our readers are so familiar with previous editions of this "*Magnum opus*," that no introduction or laudatory trumpet is called for now. When a book has reached its seventh edition within, comparatively speaking, a few years, the fact itself furnishes a test of merit and usefulness which the medical profession are not slow to recognise and rate at its proper value.

The preface states that, while many articles which had become obsolete have been omitted from this edition, yet more than 200 pages have been added to the extent of the sixth, which exceeded the fifth by 150 pages. Two new chapters have been added—one on Waters, the other on the Administration of Medicines; and Mr. Macnamara makes due acknowledgment of the labours of Dr. Hewitt, not only for the great improvement in the botanical descriptions, and the addition of a useful tabular classification of plants and vegetable products used in medicine; but also "for his unwearied supervision of the rest of the volume."

Whether the name of the late Dr. Neligan ought to be ignored or continued in this work is discussed at length in the preface. We shall not enter into that question here, further than to say that, in our opinion, Mr. Macnamara has acted wisely in retaining the name of Neligan as he has done. To ignore the name of the man who projected, wrote, and carried through no less than five editions of a standard work, were an injustice to his memory. The basis and plan of the work is still Neligan's, while the work of Professor Macnamara is so clearly distinguished, and so well appreciated by all whose opinion is worth anything, that it would be no small injustice to his reputation to allow any excuse whatever for the statement that he committed, what he never did, and, we are sure, never will commit, the literary dishonesty of entering into another man's labours without frank and open acknowledgment of the fact.

The mode of arrangement of the seventh is the same as in previous editions of this book. The botanical part is much improved, and so is the chemical; and very many useful additions and alterations are made throughout the bulk of the volume, which we cannot specify or illustrate, save by giving quotations at inconvenient length. The index is much improved and extended, and cross references are given which will much reduce the work of the student and practitioner.

We shall make a few remarks on the two new chapters; and first on "Chapter XXI.—Waters." Professor Macnamara divides waters into three great classes—fresh waters, sea waters, and mineral waters. He commences with distilled water, passes under review the therapeutic value of fresh waters, then of sea waters, and finally of mineral waters. This arrangement he follows, "nature herself apparently having adopted it;" but admits that "when we come to the subdivision of mineral waters, much will arise to perplex us." He then proceeds as follows:—

"The first classification adopted by the older writers was founded upon their sensible properties, the most remarkable, perhaps, of which is their temperature, mineral waters having been by them subdivided into cold waters and hot waters. But increased experience soon demonstrated the great difficulties attendant upon this system of classification; for though in extreme cases the contrast was well-marked, as between the classic Styx in Arcadia, the temperature of which is 33°, and the Geysers, or boiling springs of Iceland, the temperature of which is 212°, sufficiently elevated to boil an egg, still the differences of temperature pass so imperceptibly into each other, that it frequently becomes a matter of difficulty to decide to which class the mineral water should be referred; besides which, waters differing from each other in temperature but possessed of similar chemical composition, and of closely analogous remedial powers, would, by such a system of classification, appear in different classes. A classification founded upon their therapeutic properties appears to me, in our present state of knowledge upon the subject, impracticable, those most widely differing in their chemical and physical properties being equally vaunted in the treatment of the same classes of diseases. For the purposes of this work I consider it sufficient to discuss them under the following heads—Sulphurous, Chalybeate, and Saline waters. The special therapeutic advantages of all these several varieties of water will be most conveniently discussed under their respective headings. Here it will be sufficient to remark in general terms that more than a fair share of the occurring benefits attendant upon a sojourn at even the most celebrated of the Spas should not be ascribed to them Something must be allowed for change of climate and of scene; agreeable society; regularity of diet and of hours; open air exercise; and, above all, release from the toils of business and relief from mental worry. So fully impressed were the ancient Romans with the value of these most important items in a course of mineral water treatment, that the following lines were inscribed over the baths of Antoninus:—

'Curæ vacuus hunc adeas locum,
Ut morborum vacuus abire queas;
Non enim hic curatur qui curat.'"

Under the head, "Sulphurous Waters," we find valuable information about the springs at Aix-la-Chapelle, Baden, Aix-les-Bains, Harrowgate, Strathpeffer, in Scotland; Lisdoonvarna, in Ireland; and Nenndorff, in Hesse. Under Class II., "Chalybeate Waters," we are referred to Lisdoonvarna, Harrowgate, Tunbridge Wells, Sandrock, Spa, and Schwalbach. Under Class III., "Saline Mineral Waters" (which are subdivided into *Alkaline, Aperient,* and *Calcareous*), we are referred to the thermal spas of Vichy, Carlsbad, and Ems; and to the cold springs of Vals, Fachingen, Seltzers, and Marienbad.

Further, we are given a considerable amount of knowledge most useful to the prescriber as regards the aperient saline waters of Pullna, Seidlitz, Kissengen, Leamington, Baden-Baden, Wiesbaden, Homburgh, and Cheltenham, as well as particu-

lars of the calcareous or earthy springs of Wildungen, Leuk, Lippspringe, Weissenburg, Bath, and Scarborough. In addition to the foregoing varieties, which, according to Mr. Macnamara, undoubtedly possess more or less of saline matter to account for their real or a reputed efficacy in the treatment of the several diseases for the relief of which they have gained their reputation, there is further mention made of a class of waters, which, possessing no other character to recommend them than a more or less elevated temperature, and a greater or less quantity of free gases, have still secured a high position in public estimation. The most remarkable of these—the *indifferent thermal springs*—are the waters of Gastein, of Teplitz, of Wildbad, of Warmbrunn, and of Pfaffers, on the Continent; and those of Clifton Hot Wells, and of Buxton, at home.

Another new chapter—No. XXIII., on the Administration of Medicines—is a most excellent addition to the volume of 1864, and is specially intended for the edification of medical students, who were sadly in want of it, though not more so than many duly qualified practitioners. We must, with all respect for the learned Professor, take exception to his advice concerning the alleged absurdity of writing the directions in a prescription in Latin. We think that for the honour of our profession, if it is to hold its own among the other professions, there should be no pandering to ignorance in any shape. Far better would it be to abolish altogether the writing of any part of a prescription in that system of symbolism, which, by a great stretch of charitable courtesy may be called 'Latin;' than to write one half in abbreviated doggrel, and the other half in English; because, forsooth, *the dispenser is not able to translate it.* Men who take on them to dispense physicians' prescriptions, should be compelled to learn the language of written medicines. At any rate, this should be in Ireland, where the Apothecaries' Company has a monopoly of compounding, and ought to be compelled by the profession to have its monopolized business well done in that respect.

At the conclusion of this chapter, Mr. Macnamara very properly warns the young practitioner against routine prescribing, and shows the evils which are certain to result from neglect of this wholesome advice. There is a very good posological table, and a large and well-selected set of prescriptions in this volume, which is further enriched by the addition of an appendix, consisting of a classification of the chief plants used in medicine, together with the preparations of those which are included in the British Pharmacopœia, arranged according to the natural system. This appendix is the work of Dr. Hewitt, who has herein shown himself to be well qualified to perform the part allotted to him, and whose assistance, in other parts of the book, is fully acknowledged by Professor Macnamara. For the practitioner, we know of no book on this subject at all so useful as this is; for the Dublin medical student it is a *sine quâ non*, and medical students elsewhere cannot get so good a book in the English language, as Macnamara's Pharmacopœia.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 19, 1868.

THE LATE SIR DAVID BREWSTER.

OUR readers will remember how, when the learned President of the British Association for the Advancement of Science was seized with a fainting fit, on the platform, at the last year's meeting, we naturally gave expression to some forebodings lest he should soon be called away from the sphere of his labours. So it has been, and the veteran philosopher's earthly career closed on the 10th inst. We cannot call his death premature, for he had reached the age of 86, and from the earlier years of the century had been known as a careful and accurate man of science. Full of years and full of honour, he leaves a name upon which the historian of science will gladly linger as one of the brightest amongst a brilliant galaxy.

His M.A. degree was taken at Edinburgh, in 1800, and now only BROUGHAM remains of the great men who shed such lustre on the Modern Athens 60 years ago. He had been intended for the Scotch Established Church, but indifferent health, and, doubtless, an insatiable thirst to pry into the secrets of nature, determined him to devote his life to science. He commenced those investigations on light, with which his name has ever since been intimately associated, and in 1807 the University of Aberdeen conferred upon him the degree of LL.D. The next year he was admitted a Fellow of the Royal Society of Edinburgh; but his fame attracted homage also from the south. Cambridge enrolled him M.A.; Oxford made him D.C.L., and other honours were showered upon him. He projected and successfully carried out the "Edinburgh Encyclopædia," which was not completed till 1830. But great as his editorial labours were on this important work, he found time for other contributions to science.

In 1813 appeared his treatise on "New Philosophical Instruments," in which his optical studies were directed to illumination of all kinds, and most particularly to lighthouses. He next sent a paper to the Royal Society of London, "On some Properties of Light," in which he dealt with the phenomena of polarization. Then came another paper "On the Polarization of Light by Reflection." In these he enunciated most important facts, and cleared the way for further investigations. He was elected a Fellow of the Society, and the Copley Medal was awarded to him (1815.)

His name next became more popularly known as the inventor, in 1816, of the Kaleidoscope. Working on in the same field of optics, he received, two years later, the (1818) Rumford Medal of the Royal Society, for his further discoveries respecting polarization. He next seems to take a still higher stand, by adding to his work the conduct of the "Edinburgh Philosophical Journal," which he started, jointly with his friend Professor JAMESON. This he afterwards carried on by himself, as the "Edinburgh Journal of Science." The sixteen volumes that were published, contain numerous articles from his pen. Other medals were awarded him, two by the Royal Society of Edinburgh, of which he was naturally a leading Fellow, being several years Vice-President. In 1825 he became Corresponding Member of the French Institute, and, on the decease of BERZELIUS, in 1849, was promoted to be an Associate of that illustrious body. He published, in 1827, his valuable "Account of a New System of Illumination for Lighthouses," yet for six years his suggestions were not adopted. It was left for Scotland to make a trial of his plan in 1833, when it was found so successful, that from that experiment we may say the history of modern improvement commences. Thus we see, brilliant as had been his career, and with no rival to compete, the advice of the great philosopher in a matter involving life and property was not to be at once

adopted by the red-tape authorities to whom Government is committed. The merits of the learned doctor were, however, not to be disguised, and in 1831, the *honour*—should it be called?—of Knighthood was conferred upon him. In what other country are the services of the first minds of the age *recognised* by throwing them the *lowest* distinction conferred by the crown? Strange, indeed, it is, that the aristocracy of intellect should be suffered for the most part only at a distance, while wealth—well or ill-gotten—should be invited within the charmed circle of the patricians! Little wonder that genius has sometimes scorned the proffered distinction—that poets, philosophers, and patient workers in the world of science, literature, and art, have pushed aside the baubles they were offered to share with mayors, who gave dinners to royalty or courtiers who stood near sovereigns and princes in the capacity of ornamental flunkies. To return to BREWSTER. With one or two others he had planned the British Association, of which the first meeting took place at York in 1831. He continued to be interested in it all along, and was present, as our readers are aware, at the meeting last year at Dundee (see report in numbers of MEDICAL PRESS AND CIRCULAR for August and September).

Sir DAVID BREWSTER was for many years the Principal of the United College at St. Andrews, and as such, some of our readers may possess his autograph upon the diploma of that ancient University. For more than thirty years he lived at St. Andrews, and there pursued his studies. In 1859, he was elected Principal and vice-Chancellor of the sister university of Edinburgh, at which, as we have already stated, he graduated in arts in 1800. Thus, nearly three-score years of toil passed away from the capping of the young M.A., to his installation as Principal of the University where he first studied. Yet almost another decade has gone by before the Nestor of science closes his honourable career.

He has left a grand legacy in his works, but, perhaps, a still grander one in the example of a life-long devotion to work, and the trust of one who spent his life in exploring nature's mysteries, in the goodness and wisdom of nature's God.

We have mentioned several of his writings, and many others are known to scientific men. We will but name one or two more popular works which cannot be omitted even in such a brief notice as this. His treatise on "Natural Magic," will amuse and instruct even young people. So also will his "Life of Newton," which is, however, a more important work, from a scientific and literary point of view.

His "Martyrs of Science" possesses a charm which will never fail, and is a specimen of brief biographical sketches which ought to be read by all. Lastly, we must mention his "More Worlds than one; the Creed of the Philosopher and the Hope of the Christian," in which he enters into the region of metaphysics, and displays a power of debate which those who took an opposite view could not fail to respect. The work was a reply to Dr. Whewell's "Plurality of Worlds," an essay in which the learned Master of Trin. Coll., Cam., denied the possibility of animated beings inhabiting the other planets of the solar system. Sir DAVID BREWSTER took the opposite view, maintained with great power that our knowledge by no means precludes us from thinking that the other fragments of our system may be peopled with intelligent beings, but that their existence was rather to be anticipated, and would only be a natural exercise, so far as we can tell, of the Infinite Power and Wisdom of the Supreme Ruler.

We need scarcely remind our readers that Sir DAVID BREWSTER continued to enjoy his fine intellect to the last, and only very lately used that splendid debating power to expose the fabricated correspondence between PASCAL and NEWTON, which M. CHASLES presented to the Academy of Sciences of Paris last year. Sir DAVID, as we have seen, was Sir ISAAC NEWTON's biographer; he alone of authors had seen the MSS. of NEWTON, which are preserved by the Earl of PORTSMOUTH, and he vindicated in the *Athenæum* and other journals the honour of his great countryman, and completely proved that a gross forgery had been practised. As we commented upon the discussion several times during its progress, it is unnecessary to say more on the subject.

The illustrious philosopher, whose memory we have so feebly commemorated, leaves a son, Lieutenant-Colonel DAVID EDWARD BREWSTER, of the Indian Army, a gentleman now upwards of fifty years of age.

THE SCOTCH UNIVERSITIES AND THE REFORM BILL.

WE briefly alluded last week to the speech of Mr. DUNCAN M'LAREN at Edinburgh, and deprecated the manner in which he attempted to disparage the claims of medical graduates to the franchise. This speech is a direct challenge to these gentlemen, and, in fact, to the whole profession. We had hoped that the day had long since passed by when any one who has had the privilege of putting M.P. to his name should be found ready to heap insult on a learned profession, and argue that its members are unworthy to exercise the political rights afforded to ten-pound householders. Of course, Mr. M'LAREN is profoundly ignorant of the bearings of the whole question. This is obvious, not only from the general tone of his remarks, but from his mis-statements of the facts. Unless he has been very badly reported, he spoke of St. Andrews as a manufactory of doctors, and said something about her turning out 600 in 1862, and then went on to say the majority of these lived in England or Ireland. For a full explanation of this matter we refer to the memorandum to Mr. DISRAELI (p. 162.) As is well-known, at the present time, very few medical men can graduate at St. Andrews under the new regulations, so that the number is actually rapidly decreasing. Under the proposed arrangement of uniting St. Andrews with Edinburgh, we doubt if the Medical Graduates would reach 2000. But, apart from all numbers, will any one say why a Medical Graduate should not have a vote as well as a clerical one? There has, perhaps, never been proposed a more flagrant injustice than would be the exclusion of the Medical Graduates from the franchise. Parliament has assembled, and the Scotch Reform Bill is already engaging attention; and unless the Government is prepared to deal out even-handed justice, it will behove the Medical Profession throughout the three kingdoms to denounce the plot that is being laid, and to bring its influence to bear upon the Legislature. Let it be thoroughly understood that the attempt to deprive the Medical Graduates of the franchise is but an effort to create a petty close constituency that can easily be manipulated, and we may appeal from the existing Government to the Opposition with every prospect of obtaining a hearing. But it is

said the doctors will swamp the non-medical voters. Be it so—what then? Do not the clergy swamp the laity at Oxford, Cambridge, and Dublin? But what would be thought of a plan to deprive all clergymen of their university franchise? Such a proposal would raise an outcry through the length and breadth of the land, and decide the fate of the Ministry that had the hardihood to suggest it. Manifest injustice of this kind will never find favour with Englishmen, and only a frank acknowledgment that they have been misled by interested parties can save those who have charge of the Scotch Reform Bill from well-deserved obliquy.

As for Scotch members, who, like Mr. M'LAREN, do not take the trouble to acquaint themselves with the facts, they should be told very promptly and very decisively by such of their constituents as are interested, that this question, apparently so small, will be made the touchstone of their principles, that unless they vote for justice to the medical graduates every medical man will at the next election use all his influence to prevent their return, and that throwing off the usual lethargy of the profession, every medical man will work hard and canvass all his patients in order to secure his rights. Then there is the Association of St. Andrews Graduates. The members are scattered widely throughout the constituencies, but every one can bring to bear considerable influence on his own member. This individual influence should at once be exercised, besides which the association would, we think, do well to make arrangements for an active campaign.

Let it clearly be understood that even if defeated in this first object, the Association will not dissolve, but will at once set to work to agitate for the repeal of the obnoxious clause, and will organize its forces to bring collective opposition to the return of any member who does not support the right of medical graduates to vote for their university. Action of this kind, if persevered in, cannot fail, and it may well begin with persons who, like Mr. M'LAREN, distort the facts and give way to narrow prejudices against all classes, but the great ten-pounder, who is to be conciliated at all hazards. For our part we would rather trust these newly enfranchised householders for even-handed justice than self-styled "liberals" of Mr. M'LAREN's stamp.

Notes on Current Topics.

The Cantor Lectures.

THE lectures given under this name at the Society of Arts, and of which we are now publishing Dr. Letheby's learned course on "Food," are in commemoration of the late Dr. Cantor, of the East India Company's service, who bequeathed £5000 to the Society. The council devotes yearly a certain sum to lectures called after the successful Indian surgeon. Some of them have been very well attended, and this course of Dr. Letheby's has been so popular that the rooms were crowded to suffocation. No doubt some of this interest arises from the great attention the subject has recently excited among all classes, besides which, the well-known eloquence of the lecturer would be sure to attract an unusually large audience. Finding the immense amount of matter that Dr. Letheby has condensed into his lectures, it affords us great pleasure to be able to give them *in extenso* to our readers, who, we are sure, when they are completed, will find in them an exhaustive and complete treatise on Food. To have condensed into four lectures such a mass of material must have involved long labour, and may well be said to constitute a triumph in the art of lecturing.

Food for the People.

IT will interest some of our readers just now to learn that this subject is treated in an agreeable manner in the current number of the *Contemporary Review*. The article, signed Benjamin Shaw, enumerates the several methods that have been devised to preserve meat in South America and Australia, so as to make it serve as food for our countrymen. It is also very properly pointed out that no process of preserving the meat will make bad meat good, and that attention must, therefore, be given to secure that the animals are killed in fit condition. It has been too common to kill them "off the drift"—that is, immediately after they have been driven from the wilds, and before the excitement and terror of the chase have passed away. This is not the way to get good beef. Butchers at home know the necessity of fattening animals and letting them rest a day or two before they are killed. We trust this point will obtain the attention it deserves. Already, we believe, one or two proprietors are alive to this, and intend to devote their energies to the breeding and fattening of South American beasts with a view of utilizing the meat.

We take this opportunity of mentioning that other articles in this *Review* have afforded us unusual pleasure. We may name, as most within our province, that on the Education of Women and that on the London Press. In the latter, the *Spectator*, the *Guardian*, and the *Nonconformist* are subjected to fair criticism, and their merits pointed out. After this the reader will understand that, though conducted by a Dean of the Church, the liberality of the *Contemporary Review* is as marked as its lofty tone and high principles.

New Words in Medical Reading.

THE letter of Dr. Carey, which appeared in our impression of the 5th inst., calls in other expressions of opinion equally pertinent. It is undeniable that a tendency has been visible lately to use new-fangled words where plain English would suffice. Medical literature has long been notorious for its dry, uninteresting character. For our part we never could see the force of that perpetual outcry against a popular style which is answerable for no small portion of the obscurity that envelopes our annals. Our greatest teachers have adopted a thoroughly popular style, and have not unfrequently employed phraseology, which, if ventured upon by an aspirant in the present day, would infallibly call down upon him the condemnation of those would-be critics whose aim seems to be to make medical writings unintelligible. Look at the lucid lectures of Sir Thomas Watson, and the graphic descriptions of the lamented Graves! Yet who emulates their simplicity of style and expression? We should certainly recommend young authors to follow their example rather than that of the young, and, in one sense, illiterate scribes, who seem to imagine that the art of description consists in writing sentences no one can confute, because no definite meaning is to be extracted from them by the ordinary rules of English grammar.

Representation of the University of London.

THE retirement of Dr. Wood from the contest for the representation of the University of London, reduces the number of candidates now before the members of the University to four; all of whom are avowedly Liberals.

Though Dr. Wood has seen fit to withdraw, and, by so doing, has materially strengthened the already firm position of Mr. Lowe, yet it may not be out of place to remind the more junior members of the University of the essential services rendered by Dr. Wood, in support of their interests many years ago.

In behalf of the Medical Graduates, Dr. Wood was unremitting in his efforts to secure for them those privileges, and that position, to which the severe examinations of the University gave them a most unquestionable claim.

It was Dr. Wood who drew the Medical Graduates' Act, by which the University of London Graduates were placed upon an equality with those of the older Universities, and who took legal charge of this bill in its progress through the House.

Of the numerous deputations that went to the Government on medical business, Dr. Wood was, almost invariably, the leading spokesman. It was Dr. Wood also who had the chief hand in pointing out, and securing a remedy for, the injustice done to the Medical Graduates by the provisions of the Lunacy Regulation and Vaccination Acts —these being so worded, that an M.D. of London was not, by virtue of his degree, able to sign a certificate in lunacy, or of the vaccination of a child.

It is needless to say that all these important points were not gained without much labour and sacrifice of valuable time, and it was gratifying to find that Dr. Wood, together with Dr. Gull, were elected to seats on the senate of the University, being the first of the Graduates who were thus honoured.

From what we have learned, it appears that Dr. Wood yielded to pressing invitation, in allowing his name to be put forth as a candidate for the representation of the University, and obtained, with but little effort, very numerous supporters, so that his withdrawal in favour of Mr. Lowe will tend to secure the return of that experienced and active politician as the member for the London University.

The London Student.

THE prospectus has been issued of a new Monthly Journal under the name of *The London Student*.

The new periodical will devote itself altogether to the subject of education, and collegiate education in London in particular. The prospectus says:—

"*The London Student* will endeavour to reflect the whole educational movement, supplying essays, both theoretical and practical, by practised writers, upon the principal questions, reviews of educational books, and a chronicle of educational occurrences, besides throwing open a wide arena for discussion in the form of correspondence.

"It subject is education in the widest sense, including, besides general cultivation, all the forms of professional education, artistic education, technical and popular education.

"It will place London education in the foreground, and will address itself more particularly to the student-world of London; the colleges and school of which has certain very valuable characteristics—*e. g.* the professional system in full vigour, a great variety of studies, cheapness of instruction, freedom from religious tests, and the advantage inseparable from a metropolitan position, neighbourhood to the largest museums, libraries, and scientific collections.

"Under one disadvantage, however, it as yet labours. The different schools which compose it, being scattered over a large space, have, as a rule, no intercourse with each other, and are not commonly regarded as forming one whole. This want of corporate life leads to many malarrangements, and to much waste of power.

"*The London Student* will endeavour to lead the students of London to look beyond their own special colleges, and to think of themselves as belonging to a vast and splendid university—a university in an especial manner impregnated with the life of the time. It will also contain a chronicle of any occurrences in the London University or College world which London students might desire to hear of, and thus afford them the means of knowing more of each other and of their teachers. The Magazine will be under the editorship of Professor J. R. Seeley, of University College; Dr. Headland, Professor of Materia Medica at Charing-cross Medical College; and J. W. Hales, Esq., late Fellow of Christ's College, Cambridge. The first number will appear at an early date, and will be published by Messrs. Churchill, of 11, New Burlington-street, to whose care communications for the editors may be addressed. Each number will consist of 64 pages, price one shilling.

Typhoid Fever and Poisoned Water.

THE *United Service Gazette* publishes the following extract from the report of the Registrar of the District, in reference to the recent outbreak of fever at the Royal Marine Barracks at Stonehouse:—

"The water which was used by the men from a well adjoining the new wing of the barracks is clear and sparkling, and apparently much better than that supplied by the Devonport water company. In consequence of its being much in requisition, there was a great drain from its source, which, I have every reason to believe, is a very large natural cavern, one of those which are so often found in the limestone formation. This cavern is upwards of 500 ft. in length, and over or on its sides about 30 houses have been built. Persons who do not know of its existence have wondered how it is that their cesspits have not required to be emptied, which, however, is no wonder to me, for I feel convinced that many of the cesspits drain into it. When the foundation was making for the new wing of the barracks, I intimated to the clerk of the works the existence of a large cavern, running N.E. to S.W., and it was ultimately cut into, showing its presence within about 50 feet from the top of this very well. There is also a small burial-ground, not now in use, about 50 feet from the top of this well, and only about 150 yards from it."

Taxation of London Charities.

WE hear that a bill will be introduced into Parliament in the coming session to exempt Charitable Institutions in London from poor-rates. Undoubtedly, such a measure, under judicious restrictions, would deserve and receive considerable attention from the Legislature; but if it is intended to apply, as we believe it is, to all Charitable Institutions, we fear it has not the least chance of being adopted. We venture to say that there are many foundations, *soi-disant* charitable, which neither require nor merit exemption from local taxation. Many such are endowed with enormous incomes, and would find as much difficulty

in getting rid of the money saved as in paying the poor-rates. Others are mere private speculations, and of very doubtful utility, and not, therefore, of a nature to merit exemption. We should, therefore, counsel the promoters of the measure to strike out some plan of selection which may, as far as possible, confine the operation of the proposed bill to the numerous charities whose circumstances really demand such relief. Otherwise, we think the parochial authorities cannot be expected to assent to the measure.

Insalubri v of Cast-iron Stoves.

THE *Gazette Médicale* of February 1st says, that the Paris Academy of Medecine had a debate on this question at their last meeting. Dr. Carret had previously found that when shut up in a room, where a heat of 122 degrees Fahrenheit was thrown off from a cast-iron stove, he had insupportable headache after half an hour, whereas he did not experience this when a stove of fayence or sheet-iron was used. It was also known that iron was permeable to gases. But recently Messrs. Sainte-Clair, Deville, and Troost, analysed the air circulating round cast-iron stoves which were heated to a high degree, and found a large amount of hydrogen and carbonic acid, and by this they were convinced that cast-iron is more permeable to gases than sheet-iron, and more unhealthy.

Charcoal Filters.

FROM the Report of the London and General Water Purifying Company, just issued, it would appear that the public are very negligent respecting the quality of the water they drink; for the system of filtering the water at the moment of drawing, by means of the cistern filter does not spread so rapidly as we have a right to expect. We are glad, however, to learn that the profession appreciates the system. One-seventh of the filters disposed of were to medical men. The Board regret that Government did not invite the Company to tender for supplying the Abyssinian expedition with pocket-filters. At the Broadmead Asylum this system is reported to give satisfaction, all the water, 60,000 gallons per day, being thus filtered. We notice with pleasure that, in spite of the general depression, the company do not any longer re-burn the charcoal after it has been in use some time, doubt having been thrown upon the value of re-burnt charcoal. They now, in all cases, supply new charcoal when the filters are recharged. We have had one of the company's filters in our own cistern for nearly two years, and are so satisfied with it that we hope their use will rapidly extend, and, consequently, that next year the report may close with a more favourable balance-sheet. It seems, however, that only in times of alarm, when some terrible epidemic is raging, do any sanitary measures find favour. How many lives are sacrificed to this apathy which refuses to employ preventive measures!

Anti-Scorbutics.

THE druggists and provision dealers who have been in the enjoyment of the trade in the supply of lime-juice to our merchant shipping, are virtuously indignant at the rejection by the inspectors under the recent Act, of specimens far above the average quality of that hitherto usually supplied to sea-going vessels—a most cogent evidence of the necessity of the provisions of the Act. We trust that the inspecto will rigorously exact the standard set forth by the Government for the quality of this most important requirement, without the slightest regard to the clamour of interested persons.

The Coronership for West Middlesex.

THE canvass which has been so vigorously prosecuted by the candidates is coming to a close. The nomination takes place at Brentford, on this day (Wednesday) and the poll will be taken on Friday next. Three gentlemen, Dr. Hardwicke, Dr. Diplock, and Mr. Walter, are going to a contest and each expresses his confidence of success. Dr. Hardwicke, as the Deputy-Coroner, and Medical Officer of Health for Paddington, is at present the favoured candidate. Dr. Diplock has so urgently pressed his claims on the electors that he is expected, if he should not gain a majority, to receive a very large support; while Mr. Walter, who, under other circumstances would have no chance at all, may possibly profit by the division of the medical interest and step in, while the two more probable candidates are contending for the prize. What a contrast the competition amongst such men affords to the appointment by the Corporation of the City of Dublin to a similar position! In the one instance, gentlemen of talent and zeal contending to be permitted to serve the public, in the other, political and personal jobbery in its most objectionable form.

Variola in the South Midland District.

WE observe by the Quarterly Registration Returns that an excessive proportion of small-pox has manifested itself in the districts adjoining London, in some places amounting to a serious epidemic. At Luton the number of deaths has been 45, at Hertford 20, and a smaller number are recorded as having occurred in Hatfield, Harpenden, Ware, and other localities in the same district. The general prevalence of the disease is not at all such as to cause alarm as to the invasion of the metropolis, but the occurrence of an increased mortality from this cause so close to London ought to put the authorities more on the alert than they have yet been as to the enforcement of the new Act for Compulsory Vaccination.

Emigrant Ships.

WHILE human life is exposed to so many casualties, it is somewhat wonderful, to say the least, that men take no more precautions to avoid them. Much as they value existence, they are too often unaccountably reckless of it, placing themselves in danger, if apparently it answers their purpose to do so, without a moment's thought of the consequences. If an accurate estimate of those deaths which, by ordinary care, might have been avoided, were laid before us, and all circumstances disclosed which led to them, it would undoubtedly strike us with astonishment. A picture of human folly would be presented to us, so strange and unlikely, that we should have great difficulty in believing it to be a true one, and should be disposed to set it aside as a caricature rather than a graphic and honest delineation of the original. We can hardly conceive of a combination of intelligence and thoughtlessness so utterly at variance as is sometimes exhibited in the conduct of men; nor of such an abandonment of themselves to mischievous influence as would almost lead us to suspect the soundness of their mental condition. How often do we hear of the miner exposing his light at the risk of sacrificing himself and others by a fearful explosion; and how often the fact is brought before us, that the dangers

of the sea are nothing to the evils which men bring upon themselves by their carelessness while crossing its treacherous waters.

We have an instance of the latter in the German emigrant ship, *Leibnitz*, which left Hamburg on the 2nd Nov. last, with 544 passengers on board. The vessel might be, for anything we know, perfectly seaworthy, but it was overcrowded to a shameful extent. In the lower part, which ought never to have received a passenger, there was no ventilation whatever, and the air was so foul that lights would not burn in it: yet 150 persons were crowded together here. There were only four closets, and below not one, so that the ship was disgustingly filthy in every part. The rations were scanty and bad, often unfit for food. The drinking-water was given out to each person at the rate of half a-pint a-day. Sickness supervened, and no wonder: but there was little medicine, and no doctor, and consequently the mortality was fearful. No fewer than 105 died during the voyage, and three more when they came into port.

It is matter of simple astonishment that people should venture across the ocean in vessels with such shameful accommodation as this. But so it is, and we must wonder on that people should be so indifferent to their own safety and that of their friends, as to make no inquiries, and avoid dangers which are so imminent. Such things cannot occur on board any of our ships. The Government have interfered for the safety and comfort of the emigrant. There are certain regulations which cannot be neglected by the ship-owner. No more passengers are allowed than there are berths to accommodate. The dietary scale is fixed. A medical man must be carried if more than 300 persons are on board, though for our own parts we see not why 250, or even less, should not be provided with medical advice as well as the higher number. An officer is appointed to visit every vessel which leaves our shores, so that such a state of things as that we have referred to can never occur. We should hope the authorities at Hamburg will awaken before long, and follow the example of other nations in looking well after the condition of their emigrant ships.

Phthisis amongst Foreign Residents in London.

Dr. Bernadet, in his late report to the Societè Francaise de Lecours, remarks on the frequency of tubercular disease in the French residents. This Society is a charity supported principally by the benevolence of Frenchmen, and is devoted to the medical relief of the distressed natives of France. Dr. Bernadet considers that the tendency to tuberculosis is the origin of most of the affections of which Frenchmen die in London.

New Obstetric Journal.

Messrs. Moorhead and Simpson, of New York, are about to issue on the 1st of May, a new "Quarterly Journal of Obstetrics and Diseases of Women and Children," to contain ninety-six pages. It is under the editorial management of Dr. Dawson, assistant to the Professor of Midwifery at the College of Physicians and Surgeons, and Dr. Noeggerath of the German Hospital and Dispensary.—The subscription will be 3 dollars.

To Certifying Surgeons.

A little work has appeared from the press of Messrs. Knight and Co., of Fleet-street, entitled "Hints to Certifying Surgeons under the Factory Acts." It is written by Mr. George Greaves, himself a certifying surgeon, and the consulting Surgeon to the Chorlton Union Hospital, an institution we have long since fully described in our columns. The duties of the persons to whom it is addressed are discussed in their twofold aspects: *First*, as to the qualifications of young persons, by age or otherwise, for work; *second*, as to reporting accidents caused by machinery. Although this little book extends to only 23 pages, the newly appointed certifying surgeon will find it very useful, as the "hints" it offers are of a practical nature, and are very clearly expressed. Reading that a woman has attempted to deceive as to the age of a child, be extracting some of the milk teeth, so as to make it appear that their permanent successors were about to appear, may well make those who have not been initiated into such practice, believe that the "hints" of Mr. Greaves are, some of them, such as will not be anticipated.

Diminution of Small-pox in Ireland.

The Poor-law Commissioners of Ireland have, last week, addressed to the Boards of Guardians a letter referring to the very satisfactory results of the existing system in the stamping out of small-pox, and requesting exact information as to the existence of the disease in any particular locality. The communication is as follows:—

Poor-law Commission Office, Dublin,
6th February, 1868.

Sir,—The Commissioners for administering the laws for relief of the poor in Ireland, desire to inform the Board of Guardians that the rapid diminution of small-pox in Ireland during recent years has, the Commissioners have reason to believe, been accelerated in a most remarkable degree during the year ended on 31st December last.

The returns of deaths by small-pox in the Workhouse Fever Hospitals in that year, compared with those of the year 1864, show only 4 deaths in comparision with 149, or 1-37th part of the number in 1864.

The returns of small-pox cases treated by the Medical Officers of Dispensaries, so far as they have yet been received, are equally satisfactory, 24 cases only having been returned as treated in the half-year ended 30th September, 1867, in comparison with 850 cases in the corresponding half-year of 1864.

It has, therefore, appeared to be very desirable to ascertain, with as much accuracy as possible, all the localities in Ireland in which small-pox is now to be found, in order that in such cases vigorous measures may be taken to complete the suppression of the disease, and prevent its revival as an epidemic.

The Guardians are therefore requested to obtain, through the members of the Board and the Union Officers, especially the Dispensary Officers, exact information as to the existence of the disease in any part of the Union at the present time, either in Dispensary or private practice, and to instruct the Clerk to report to the Commissioners the result of the inquiries which may have been made as soon as practicable, and not later than the 24th of this month.

The stringency of the law now in force to compel parents to have their children vaccinated, and to procure the prosecution of persons inoculating with the small-pox, and thus originating and spreading the disease, has, no doubt, had a material effect in producing this great change; and the Guardians will no doubt feel, in an increased degree, the importance of continuing those exertions which have already, to so great an extent, been attended by success, and which, with the aid of the provisions of the recent Sanitary Acts, may, it is hoped, finally result in the entire suppression of the disease in this country.—By order of the Commissioners,

B. Banks, Chief Clerk.

The very extraordinary diminution in the frequency of this zymotic, from 999 to 28, in the short period of three years, can hardly be calculated on as altogether either a permanent result, or one totally dependent on the existing system, yet, making every allowance for error and chance, the statistics evidence an improvement of a most important character in the public health.

From the annual report of the London Fever Hospital, presented to the meeting on Friday last, it would seem that fever is on the decrease in London. During the last six years 18,152 patients have been admitted, more than half as many as the total since the foundation of the hospital sixty years ago. That total is 32,250. It is time our efforts produced some effect.

We regret to announce the death of Dr. Herapath, the eminent toxicologist, of Bristol, at the age of 72. Dr. Herapath has been prominently concerned in toxicological investigations for nearly half a century.

On Saturday evening the Association of Medical Officers of Health had a discussion respecting Dr. Letheby's views as to the alleged connection of the late epidemic of cholera with the East London water supply. We are sorry that we have no available space for further particulars of the debate this week.

At the last meeting of the Harveian Society, a committee was appointed to investigate the action of drugs. At the next meeting a paper is announced by Mr. W. Adams on Spinal Curvature.

Miss Ettles, of Inverness, has given £1000 to the University of Edinburgh, and its Faculty of Medicine.

The fever at Terling continues; fifteen new cases were announced last week. Dr. Thorne has paid another visit. It is said that a better supply of drinking water has been obtained.

We beg to draw the attention of our readers to the fact, that the Richardson testimonial will shortly close. We have already urged the claims of Dr. Richardson to a handsome recognition, and hope that those who have forgotten to enrol their names will do so before it is too late. The last day (will be seen in our advertising columns) is the 24th of March.

MEDICAL APPOINTMENTS UNDER THE DUBLIN CORPORATION.

When we exposed, in the issue of our Journal for the 13th of November, the perpetration of a job by the Dublin Town Council of the class which has obtained for that body the character for audacious disregard of public opinion, and of even the pretence of propriety in the disposition of their patronage, we hardly expected to have been so soon called on to drag into the light another transaction of a similar, or, if possible, more objectionable nature.

The public papers of Friday last put us in possession of as much information on the matter as is allowed to meet the public eye; but we have a few little facts which may serve as a fitting corollary, and which, in their naked truth, will be, perhaps, more forcible than if garnished with any comment of ours.

It will be learned, on reference to The Medical Press and Circular of the 13th Nov. last, that, in direct opposition to the evident intention of the law, and contempt for justice, the Corporation arrived at the determination that, in future, the medical evidence in coroners' inquests under their jurisdiction should be given by two individuals, instead of being taken from the medical man who might have attended the deceased person, and thereby acquired some information on the cause of death. Probably the Dublin Town Council would have given themselves as little concern on this matter as they do to many other of their public duties; but there were two coroners' sons to be settled in life at the public expense, and these two gentlemen, possessed of no more special qualification in medico-legal investigation than John Doe and Richard Roe, were accordingly appointed medical witnesses for the city of Dublin.

Within the last fortnight the coroner, Dr. Kirwan, died, and the patronage of the office was at the disposal of the Town Council. The anxiety of mind of the dominant party in the Corporation to do credit to themselves, add dignity to the office of judge of inquests, and provide an efficient security for the city of Dublin against deaths from negligence or criminal, intention, it is to be presumed, prevented their giving due attention to the interests of the city, for we learn that the usual meeting on the 6th of February was postponed after a vain delay of an hour and a-half, for want of a sufficient attendance to make a *quorum*, the Town Clerk having most reprehensibly omitted to put on the notice-paper such a financial job or political "scrimmage" as might attract an assembly.

On Thursday last, however, a meeting, such as has not been the wont in the City Hall, assembled for the appointment of a coroner. It had been rumoured that a medical town councillor, whose name had been mentioned, would be elected as a matter of course, but as he had withdrawn his claims on the votes of his fellows, the choice lay between only two gentlemen—Dr. N. C. Whyte and Dr. Butler, of whom, by an enormous majority—almost with the unanimity of the chamber—the former was chosen.

Have the readers of the papers ever inquired who Dr. Whyte is, and what he knows about forensic medicine? May we be permitted to supply the answer?

Dr. N. C. Whyte is a member of the College of Surgeons of England, and has no medical qualification whatever. In 1858 he was one of the medical officers of the 2nd Stafford Militia. Shortly after, he went to Italy as one of the Pope's brigade. On the breaking up of that force he retired into private life, and as his name does not appear in the Medical Directory, and only at the address of "Curragh Camp" in the Medical Register, we have no clue as to the extent of his forensic acquirements, or his qualification for the office of city coroner. A couple of years ago he again appeared on the public stage, not in a medical capacity at all, but as the secretary to the extinct organization then known as the "National Association"—the impersonation of the extremest and most intolerant policy of the ultra-republican party in Ireland—a connection with which would be held anywhere but in the Dublin Corporation as a declaration of war against political moderation, and a disqualification for any public position requiring an unbiassed judgment. The National Association having merged in a condition of insolvency, Dr. N. C. Whyte became a charge on the Corporation, and they have accordingly disposed of him in the judgeship of the Coroner's Court of the City of Dublin.

The only anxiety expressed at all by the members of the Corporation, if we may judge from the published reports, was that the previous job, which placed the coroner's son in the position of medico-legal adviser to the court, should be perpetuated, and in open council a pledge to this effect was demanded from Dr. Whyte. However, not even the broadest hint could extract such a promise from that gentleman, and it is rumoured that the coroner's son, in spite of the dictum of the Corporation, may probably be forestalled by another gentleman of equal medico-legal qualification, but enjoying greater favour with the new coroner.

We could not safely characterise this transaction in the language which we feel that it deserves. It would be an absurdity for us to trouble our readers with an argument to show that Dr. N. C. Whyte is not the best man who could have been selected for such an office; for, if he possesses any qualification which goes, even in a small degree, to mitigat

his complete unsuitability, we are in ignorance of what it may be. We say enough when we express the opinion that, in the long and sore reckoning of their financial, political, religious, and personal jobbery in abuse of the trust reposed in them by the citizens, no more flagrant instance than this has occurred; and in face of the fact that such an act can be perpetrated with the unanimity of the chamber, people who respect themselves are bound to hold aloof from connection with such an assembly.

Correspondence.

"PECULIAR PEOPLE."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was, I confess, rather amused, and also somewhat indignant, when reading the note on "Peculiar People" in your Current Topics of this week. Really the writer's egotism and dogmatism is marvellous: firstly, he begins with the acknowledged right of a British subject to make a "fool" of himself, if it so please him; and then, quietly mounts his own peculiar hobbies, ego and dogma, and comments upon that right. Whilst on the former, he dares to indulge in judgment upon the peculiar (it may be) views of individuals, as regards their relation to an Almighty Power, and speaks in terms of approbation of a "prosecution for manslaughter" of persons who allowed (he says) their child to die, because they believed in "no curative power of man," but in the direct interposition of the Almighty. How does *he* know that man's remedies would have saved the child? How dare *he* say what the jury declined saying when they "acquitted" the case, viz,—that the child need not have died, and the parents' neglect killed it? Was the mother's loving, tender, untiring, and ceaseless fortnight's attendance, night and day, neglect? Was the father's spare moments, spent in prayer for, or attendance on, his child, neglect? Verily there *is* "liberty in Great Britain" with a vengeance, when a man's private religious belief is to be hauled over, and subjected to the scrutiny of any stranger, who has impertinence enough to meddle with it. Though I certainly should not have employed the means they used for the recovery of a child of mine, were it ill, yet, I would have used *no* means *without* the prayers of myself, and, if it so pleased me, of elders, deacons, ministers, clergymen, priest, or any whom I thought were godly, for I read "the prayer of a righteous man availeth much," and if my hobby, or my faith, lead me to put trust in the direct interposition of the Almighty, to be gained by prayer, "yet for this will I be inquired of," I do not think, Mr. Editor, I have a right to be laughed at for my trust and confidence in Him, "without whom we are powerless, either with, or not with, human help and aid." Again, he mounts hobby No. 2, and makes an assertion, which is untenable—namely, that the "disbelief in human aid would not in the slightest degree protect them from the just punishment of neglecting the proper means to save life." How is this? Do we not often hear of persons whose disbelief in human remedies causes death? The abstainer, for instance, for whom the doctor has ordered stimulants; those who do not undergo surgical operations when told 'tis the only hope of saving life; those who are told intoxicating drinks are poison, yet, going on quaffing them greedily. No! no! your writer had better dismount dogma: no law can punish me for not drinking a quart of any mixture, if I do not approve its maximum, any more than it can compel me to swallow a grain, if I have no faith in its minimum; neither can it punish my survivors for neglect of recommended means. It could interfere if I starved a child, or in case of broken limb, or such casuality, the proper means were neglected; if in infectious disease I allowed it to spread by intercourse with my fellows, &c., but whilst I, or any of the "peculiar people," break no law, but act conscientiously, and as *we* think rightly, in the sight of God and man, please Mr. Editor to allow us to be at peace, or, at least, do not have us held up for ridicule in your valuable, and far spread journal.—I am, sir, yours, &c.,

M. LIPTRATE.

London, February 5th, 1868.

[THE only two points which our correspondent makes against us are weak, simply because they are misrepresentations both of our opinions and our words. We did not say, though we have our own opinion, founded on the medical evidence, "that the child need not have died, and that the parents neglect killed it." On the contrary, we specifically declared that it was for want of proof of this that the parents were acquitted, and not because they were protected by their plea of religious peculiarity. *Secondly*, We took care to point that the privilege of every man to exercise the delusions with which he may be possessed is confined to his own person. He has a perfect right to imperil his own life, health, or comfort, by his fanaticism, but he is not entitled to injure others, and especially those whose tender age prevents their choosing for themselves. Every parent is intrusted with the care of his child, not to afford him an occasion for the exercise of his own narrow ideas, but in the expectation that no protection which circumstances afford will be neglected.—ED. M. P. & C.]

THE ABUSE OF GRATUITOUS MEDICAL AND SURGICAL ADVICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I do not remember seeing noticed in your journal an abuse which really ought not to be permitted to exist any longer. I allude to the practice of well-dressed, apparently well-to-do females, taking advantage of the freedom offered them of applying to our many hospitals and dispensaries for gratuitous medical and surgical advice.

No wonder many of us are complaining of the badness of the times, when the staffs of those institutions encourage such visitants by their especial obsequiousness *to them*, in contradistinction to the necessitous poor! This is too truly a fact, as I have been compelled to hear, and can instance cases of the kind not a few.

Surely a little discernment and distinction should be made between the two classes of people, and they of the "better class" should be informed of the intention of those institutions, or if they persist in going, should be made to contribute something substantial for the benefit of their poorer brethren and in aid of the funds of needy hospitals and dispensaries.

I need not say more on the present occasion. I would simply direct attention to this positive evil, in the hope that some alteration may be made, that our noble institutions may not continue to be perverted from their original intentions and the intentions of their present liberal donors and supporters.

By giving insertion to this short letter in your valuable paper, you will greatly oblige

"ONE WHO HAS CAUSE TO COMPLAIN."

DR. LETHEBY'S LECTURE ON FOOD.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you allow me to call the attention of your readers to the following inconsistency in Dr. Letheby's interesting lecture on food, contained in your number of the 29th ultimo. Dr. Letheby truly states in the course of that lecture that "primarily all our foods are derived from the vegetable kingdom, for *no animal* has the physiological power of associating *mineral elements*, and *forming them* into *food*." Now, this is thoroughly sound physiology, and at once shows the absurdity of the customary prescriptions of iron, phosphates, and other salts of lime, &c., as "blood food"—prescriptions which are based on ignorance or forgetfulness of all sound physiology, inasmuch as they cannot, in their mineral condition, be assimilated by the system, which, on the contrary, does its best to eject them the moment they are presented to it.

Now, the inconsistency which I wish to refer to in Dr. Letheby's lecture is his sanctioning the addition of salt or muriate of soda to bread after previously stating that the system is incapable of assimilating it. This being the case, it is a poison, incapable of affording nutriment to the animal economy, and therefore injurious to it. It is these illogical inconsistencies, and ignorance or neglect of sound physiological principles, which lead to the present unsatisfactory state of the medical art, poisons being prescribed for food.—Your obedient servant,

RICHARD GRIFFITH, Ch.M.

[THE mineral substances play the part of purveyors, and are therefore very useful—in fact, in not a few instances they are necessary. To call them poisons "incapable of affording nutriment to the animal economy, and therefore injurious to it," is a strange proceeding on the part of one attempting to correct such an authority as Dr. Letheby. What will the teetotallers say to Mr. Griffith's proposition, which necessarily includes

water? Our correspondent should not impute "ignorance" or "neglect of sound physiological principles," or "inconsistencies," to writers he has evidently failed to comprehend.—ED. M. P. & C.]

RICHARDSON'S ETHER SPRAY APPARATUS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having recently procured Richardson's ether spray apparatus, I would feel thankful to one of your readers for a detailed description of its application. Several years' absence from the country, under circumstances in which it was impossible for me to be acquainted with this discovery, will account for my ignorance in this regard. Perhaps you or some kind contributor would be good enough to direct me to where I could obtain this information *in extenso*.—I am, &c.,

A COUNTRY DOCTOR.

[OUR correspondent will find very full descriptions in the back numbers of our own and other journals for the past two years. A complete work on the subject by Dr. Richardson is in hand, and would have been completed before this time but for the demands made upon his leisure by the course of lectures now being delivered on experimental and practical medicine, with which our readers are familiar. The book will now be published, however, at an early date. It is the custom of most instrument-makers to send a series of short rules with the instrument.—ED. M. P. & C.]

SUPPRESSION OF SMALL-POX BY ISOLATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In THE MEDICAL PRESS AND CIRCULAR for February 5, are some notes on Sir J. Simpson's proposal to stamp out small-pox and other contagious diseases by *isolation* of those affected.

I should like to be allowed to draw attention to the very great success that has attended such a plan of preventing the spread of small-pox in the village of Burton-on-the-Water in Gloucestershire.

Mr. Moore, the surgeon of this village, well-known as the instituter of one of the very first of the village hospitals, and also as the discoverer of the familiar "Moore's Test" for diabetic sugar, has been good enough to furnish me with a few notes respecting sundry outbreaks of small-pox in his district. They are as follows :—

On six different occasions has small-pox been imported into the village (which comprises over 1000 inhabitants), and on all these occasions, by strict isolation of the infected families, the disease has been entirely restricted to the house in which it originated, and has never spread to other houses.

In one case the disease appeared in a family of twelve persons; all were vaccinated, and, with the exception of one servant, who got the disease in a very mild form, there was no extension to other members of the family.

In other neighbouring parishes, when this method of strict isolation of the sick, and those in immediate attendance upon them, has been carried out, similar fortunate results have followed. In some places where all these precautionary measures were set quite at defiance, most severe outbreaks of small-pox were witnessed.

I have ventured to send these few simple facts to THE MEDICAL PRESS AND CIRCULAR, as this subject of isolation in cases of small-pox, appears now to occupy some attention, and in the hope that medical practitioners will be induced to enforce a rigid seclusion of those who are sick, and who are in contact with the sick, from intercourse with their neighbours, for thus much danger, anxiety, and trouble may be averted from a community.

It is pleasing to find that in Gloucestershire, Jenner's own county, the Medical Profession is disposed actively to suppress anything like an outbreak of small-pox.—I am, sir, obediently yours,

JOHN C. THOROWGOOD, M.D.

February 12, 1868.

Medical News.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The lectures for this year have been announced and the tickets distributed. The Gulstonian are to be on March 4th, 6th, and 11th, by Dr. John Harley, whose subject is the "Physiological Actions and Therapeutical Uses of Conium Belladonna, and Hyoscyamus; alone and in combination with opium." The Croonian lectures are to be March 13th, 18th, and 20th, by Dr. Bence Jones, and the subject, "Matter and Force." The Lumleian lectures will be on March 25th, 27th, and April 1st, by Dr. Guy. His subject is the "Factors of the Unsound Mind; with special reference to the plea of insanity in criminal cases." The lectures are delivered at the college at five o'clock P.M. We are also informed that an additional lecture will probably be delivered this year by Dr. Wilson Fox on "Tubercle."

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At the quarterly examination held on the 11th, 12th, and 13th instants, the following gentlemen passed the first half of their examination for the letters testimonial, viz.:—Joseph Backhouse, Joseph Beatty, Richard D. Bennett, Patrick J. Bodkin, Benjamin F. Bradshaw, William Budd, John Carson, John Clancy, John J. Crean, Richard Creed, Joseph P. Doyle, Edward Fawcett, George Gloag, Frederick Hasler, John Kernan, Francis H. Lyon, George J. Mackesy, William Morrison, James Marsh, Eugene Nolan, Frederick S. Price, George H. Torrance, James F. Walker, Albert J. Watson, and Richard J. Wheeler.

TEMPERATURE OF 1867.—Mr. Glaisher reports that the mean temperature of the air in the three winter months, ending February, 1867, registered at the Royal Observatory, Greenwich, was 40·6 deg., being 1·4 above the average of the preceding 26 years; in the three spring months, ending May, 46·7 deg., being 0·4 below the average; in the three summer months, ending August, 59·8 deg., being 0·8 below the average; in the three autumn months, ending November, 49·2 deg., being 1·3 lower than the average; in December, 1867, 37·5 deg., being 1·6 lower than the average of 96 years. The highest temperature registered in 1867 in the 56 stations from which Mr. Glaisher has returns was 91·2 deg. at Royston, Herts, in August; the lowest was 0·0, at Lampeter, Cardiganshire, and also at Norton-in-Hales, Shropshire, in January, 1867.

NOTICES TO CORRESPONDENTS.

Proofs reaching authors in England on or before Friday morning, are expected to be returned to the Editor, at the office, 20, King William-street, Strand, W.C., before five P.M., on Friday afternoon. Proofs reaching authors on Friday evening or Saturday morning *must* be returned to the office by two P.M. on Saturday, which is an early closing day. Duplicate proofs are sent to authors, in order that they may correct and return one copy, and keep the other for private use. Contributions should be LEGIBLY written, on one side of the paper *only*.

All Communications and Letters must be authenticated by the name of the writer, though not necessarily for publication.

We are gratified to acknowledge a number of encouraging letters from old as well as from some of our new subscribers. Steady support like that we have lately received is most satisfactory, and spurs us to renewed vigilance in the interests of the Profession. The best thanks are offered for this, as well as for the still greater assistance some have afforded, by obtaining for us new subscribers. It is impossible to find space for remarks from all. The gentleman who has obtained six new subscribers will accept our warmest thanks. Those who have obtained a smaller number have no doubt been equally pleased with our endeavours. We hope each of our friends will see cause to assist us in the same way.

Dr. BLACK.—Enclosure received. We are glad you can commend our paper for the "terseness of its articles, and the independent spirit it maintains."

J. B.—The copies have been sent. It is very complimentary to pronounce our paper "indispensable." The article will appear in three weeks.

Mr. HIND.—We would willingly publish the case.

F.R.C.S.—The hospital is most respectably conducted. The fear of its specialty lowering your status is unfounded. The crusade against specialism is most ridiculous, and must fail.

J. BLAKE.—You can get them through any bookseller. If a long distance from one, Messrs. Churchill would probably send them by post on receipt of stamps.

HY. GROOM.—The book was published a year or more ago by Messrs. Longmans and Co.

Dr. COCKLE.—The figures are in the hands of the engraver.

Dr. CLARK, Staines.—A perusal of "The Letter of Advice" mentioned by you might be useful to us. Will you kindly forward it?

S. P. S., London.—We shall use the information placed at our disposal consistent with our position, in order to arrive at an incontrovertible conclusion, and will acquaint with the result.

Dr. EDMUNDS.—Your communication to hand; too late for this week's issue; will appear in our next.

Dr. WALTER SMITH.—Your paper on "Case of General Paralysis Subsequent to Cholera," shall appear in our next.

Dr. CHAPMAN.—Packet received. Proofs will be sent as soon as possible.

Mr. J. BAXTER LANGLEY.—"The End of an Impostor" shall appear in our next.

The Medical Press & Circular.

Dr. LETHEBY'S SECOND LECTURE ON FOOD.

COMPARATIVE DIGESTIBILITY OF FOODS—FUNCTIONS OF DIFFERENT FOODS.

(Continued from page 153.)

Nitrogenous or *proteinaceous*, or *albuminous substances*, which constitute the leading articles of diet, are evidently digested by the gastric juice and the intestinal mucus. In the former case they are converted into acid peptones, of which, according to Lehmann, there are several varieties, as *albumino-peptones*, *fribrino-peptones*, *caseino-peptones*, *gelatino-peptones*, &c., according as they are derived from albumen, fibrin, casein, gelatin, &c., and of these substances the fluid form of albumen is most easily converted; then coagulated albumen; then fibrin; then casein; and, lastly, the derivatives of albumen, gelatin, chondrin, and cartilage. The tegumentary forms of albumen, as hair, wool, feathers, &c., being entirely indigestible. Here is an example of the indigestibility of hair—it is a ball of it obtained from the alimentary canal of a cow, and has come from the calf which the cow has a habit of licking. Serpents and other animals that swallow their prey entire, digest the soft tissues and bones, but they disgorge the hair and feathers untouched.

It is difficult to speak of the comparative digestibility of different nitrogenous foods. The well-known experiments of Dr. Beaumont, on the Canadian with a fistulous opening in the stomach, and even experiments made in bottles with pepsin, do not represent the full and natural conditions of the process present, but that there are great differences in the digestibility of different animal substances, there can be no doubt. Dr. Beaumout found, in his inquiries, that soused pigs feet and soused tripe were the most digestible of all foods, and that boiled tendon of meat was the least. The following, in fact, are the times given by him for the chymification of different animal foods :—

Articles of Diet.	How Cooked.	Time of Chymification. H.	M.
Pigs feet (soused) ...	Boiled ...	1	0
Tripe (soused) ...	Do.	1	0
Eggs (whipped) ...	Raw ...	1	30
Salmon trout ...	Boiled ...	1	30
Venison steak ...	Broiled ...	1	30
Brains	Boiled ...	1	45
Ox liver	Broiled ...	2	0
Codfish (cured dry) ...	Boiled ...	2	0
Eggs	Roasted ...	2	15
Turkey	Boiled ...	2	25
Gelatine	Do.	2	30
Goose	Roasted ...	2	30
Pig (sucking) ...	Do.	2	30
Lamb	Broiled ...	2	30
Chicken	Fricasseed ...	2	45
Beef	Boiled ...	2	45
Do.	Roasted ...	3	0
Mutton	Boiled ...	3	0
Do.	Roasted ...	3	15
Oysters	Stewed ...	3	30
Cheese	Raw	3	30
Eggs	Hard boiled ...	3	30
Do.	Fried ...	3	30
Beef	Do.	4	0
Fowls	Boiled ...	4	0
Do.	Roasted ...	4	0
Ducks	Do.	4	0

Pork	Roasted ...	5	15
Tendon	Boiled ...	5	30

It is doubtful, in fact, if cheese or tendons are ever digested except in small quantity; and it is evident, from these experiments, as I shall hereafter explain, that cooking has considerable influence on the digestibility of substances.

It is a curious problem why the stomach does not digest itself, seeing that it belongs to the class of most easily digestible substances, as tripe. Hunter explained it by referring the protective power to the vital force, for when dead the stomach digests itself in common with the food contained in it; but Bernard's and Pavy's experiments have proved that this is not the right explanation, for if the legs of living frogs, or the ears of living rabbits, are introduced into the stomach of a dog through a fistulous opening in the side, they digest like other proteinaceous substances. Liebig supposed that the protective power was in the thick mucus which lined the stomach, but Pavy denuded a part of the inner walls of a dog's stomach, and found that the tissue did not digest, but, on the contrary,

quickly healed, and he is of opinion that the protective power is, in the alkaline condition of the blood, which circulates so freely through the capillaries vessels of the stomach during digestion.

Starchy substances, and *cellulose*, are digested by the ptyalin of the saliva, and the pancreatin of the pancreatic fluid, as also by the animal diastase of intestinal mucus. The solution is effected by the conversion of the starch and cellulose into a low form of sugar called *glucose*, which is freely absorbed into the circulation, or becomes changed into lactic acid, that serves so important a function in the digestion of nitrogenous matter. The time necessary for the digestion of different vegetable substances, as determined by Dr. Beaumont, is as follows :—

Articles of Diet.	How Prepared.	Time of Chymification. H.	M.
Rice	Boiled ...	1	0
Apples (sweet and mellow)	Raw ...	1	30
Sago	Boiled ...	1	45
Tapioca	Do.	2	0
Barley	Do.	2	0
Apples (sour and mellow)	Raw ...	2	0
Cabbage with vinegar	Do.	2	0
Beans	Boiled ...	2	30
Sponge Cake ...	Baked ...	2	30
Parsnips	Boiled ...	2	30
Potatoes	Roasted ...	2	30
Do.	Baked ...	2	33
Apple Dumpling ...	Boiled ...	3	0
Indian Corn Cake ...	Baked ...	3	0
Do. do. Bread ...	Do.	3	15
Carrot	Boiled ...	3	15
Wheaten Bread ...	Baked ...	3	30
Potatoes	Boiled ...	3	30
Turnips	Do.	3	30
Beets	Do.	3	45
Cabbage	Do.	4	0

It would be seen from this that the time of digestion is in proportion to the amount of cellulose or woody tissue in the food. No doubt there is a more complete solution of these matters in the small intestines, where the pancreatic fluid and intestinal mucus, aided by the alkaline condition of the fluids, exert the greatest actions on them, but it is very doubtful whether hard cellulose and woody matter are at all digested by man. Even in the case of the pig, whose digestive powers are singularly active, it is thought by Messrs. Lawes and Gilbert, from their experiments on the fattening of animals, that there is little or no digestion of these substances ; and, under any circumstances, a very prolonged contact with the secretions is necessary for their digestion. Raw starch will pass a considerable distance along the alimentary canal of man without much change, and it is only towards the end of the small intestines that the starch granules undergo marked disintegration. Those animals which feed entirely on vegetables have always a contrivance for keeping the food for a long time in contact with the secretions. It occurs as the paunch in ruminants, the crop in birds, the large cœcum in rabbits and other rodentia, and as the long alimentary canal of all of them ; but even then a large portion of the vegetable tissue passes through the bowels unchanged. Cooking, grinding, and otherwise disintegrating the tissue, helps considerably in the digestion of it.

Gum and *pectin* are probably not digested at all, for as they are unchanged by contact with the secretions, and are incapable of dialysis or absorption, they must pass through the alimentary canal without serving any purpose in nutrition.

Fatty matters are digested by the emulsifying action of the pancreatic fluid ; and by being thus broken up into extremely minute globules they are freely admitted into the lacteal vessels ; in fact, the emulsified globules of fat are seen covering the villi of the intestines, penetrating their tissues, pervading the subjacent cellular bodies, and thus entering the lacteals ; and, no doubt, the paristaltic action of the intestines contributes largely to this emulsifying process.

Saline substances are generally soluble in w: ter and are therefore easily absorbed, but when this is n t the case, as with the earthy phosphates, they are atta ked by the acid constituents of the gastric juice.

And here I may remark that the great aids o digestion are :—

1st. Proper selection of food, according to t e taste and digestive power of the individual.

2nd. Proper treatment of it as regards cook ng, flavouring and serving it.

3rd. Proper variations of it, both to its nature and treatment, so that the appetite may not fail.

4th. Exercise, warmth, and a genial disposit on.

Although much attention has been directed to the important subject of the immediate and remote functions of food, yet it must be admitted that the difficulties of the question have not been surmounted, and that we are hardly able to particularise the phenomena which a e incidental to its transformations. We can see clearly enough that its ultimate destiny is the manifestation of for e—the letting loose of the cosmical agencies which were bound up in it—when, by undergoing oxydation, it returns more or less completely to its original forms—carbonic acid, water, and ammonia ; but how and where these change occur, and what are the subsidiary phenomena, and concurrent functions, besides those of common motion and animal heat, are as yet almost unknown to us. Nor are we sufficiently acquainted with the special attributes of the principal constituents of food, as the albuminous, the fatty, the farinaceous, the saccharine, and the saline ; for although the well-known opinions of Liebig, with regard to the dynamic or force-producing functions of the nitrogenous or plastic elements of food, and of the thermotic or respiratory powers of the carbonaceous have been generally received, yet there are abundant reasons for believing that both of these classes of food may perform exactly the same functions in respect of the development of force ; and, again, it is more than probable that the nitrogenous, or plastic constituents of food may, like the carbonaceous, be oxydised and consumed in the living body, without ever entering into the composition of tissue. In these respects, therefore, there are great points of divergence from the views of Liebig.

Looking, however, at the proximate elements of food, it may, perhaps, best serve our present purpose if we enquire generally into the several functions of water, albuminoid compounds, fatty substances, farinaceous and saccharine matters, and mineral salts.

1st. *Water* is, unquestionably, of great physiological value, for as much as 75 per cent. of the muscular tissue of the animal frame is composed of it; and of the 20 lbs. of blood which an average sized adult contains in his body, about 15½ lbs. are water. It is computed, also, that not less than 30 lbs. of fluid ebb and flow daily from the blood and alimentary canal by secretion and absorption. Bidder, indeed, estimates that about 28·6 lbs. of chyle and lymph are carried daily by the thoracic duct alone into the circulation—a quantity of fluid that amounts to about one-fifth of the entire weight of the adult human body ; and, then, with regard to the excretions, we find that rather more than a pound of water is exhaled daily by the breath, about a pound and three-quarters by the skin, and not less than two pounds and three-quarters by the kidneys, making altogether about five pounds and a-half per adult daily.

These results indicate the importance of water in the functions of the animal body. It serves indeed to dissolve the food and carry it into the circulation; to effect the distribution of it throughout the system ; to dissolve effete matters, as the metamorphosed constituents of worn-out tissues, and convey them out of the body; to establish the chemical activity which is necessary for nutrition and decay; to combine mechanically with the tissues and lubricate them, so that they may perform their functions; and lastly, to evaporate by the air-passages and skin, and thus maintain the proper temperature of the body.

2nd. The second constituents of our food—namely, *albuminous, nitrogenous*, or *plastic matters*, were once, and until very recently, thought to have the sole function of constructing and repairing the muscular parts of the body; and having so entered into the composition of tissues, their oxydation and decay were attended with manifestations of force which were the working powers of the animal machine. "We see," says Liebig, "as an immediate effect of the manifestation of mechanical force, that a part of the muscular substance loses its vital properties,—its character of life; that this portion separates from the living part, and loses its capacity for growth and its power of resistance. We find that this change of properties is accompanied by the entrance of a foreign body (oxygen) into the composition of the muscular fibre; and all experience proves, that this conversion of living muscular fibre into compounds destitute of vitality, is accelerated or retarded according to the amount of force employed to produce motion. Nay, it may safely be affirmed, that they are mutually proportional; that a rapid transformation of muscular fibre, or, as it may be called, a rapid change of matter, determines a greater amount of mechanical force; and conversely, that a greater amount of mechanical motion (of mechanical force expended in motion), determines a more rapid change of matter." He further remarks that "the amount of azotized food necessary to restore the equilibrium between waste and supply is directly proportional to the amount of tissue metamorphosed," that "the amount of living matter, which in the body loses the condition of life, is, in equal temperatures, directly proportional to the mechanical effects produced in a given time." That "the amount of tissue metamorphosed in a given time may be measured by the quantity of nitrogen in the urine"; and "that the sum of the mechanical effects produced in two individuals in the same temperature, is proportional to the amount of nitrogen in their urine; whether the mechanical force has been employed in voluntary or involuntary motions; whether it has been consumed by the limbs, or by the heart and other viscera."

These are the generalizations of Liebig, and they go to show, not only that the dynamical action of the animal body depends wholly on the transformation of muscular tissue, and may be measured by the quantity of nitrogen excreted as urea; but also that no oxydation of nitrogenous matter can take place until it has passed from the condition of food to tissue, and has thus become organized. According to this view, the mechanical force of the human machine is derived entirely from its own combustion, and not from the oxydation of matters contained in the food.

For some time past there have been suspicions that this view of the case is not correct; and the doubts of physiologists have been strengthened by the circumstance that great labour might be performed for a short period without the use of a nitrogenous diet; and that while there was always a relation between the quantity of nitrogen in the food, and that excreted as urea, there was no such relation between the dynamical actions of the body and the proportions of urea. Moritz Troube, in fact, asserted in 1861, after a careful examination of the subject, that all muscular force was derived from the oxydation of fat and hydrocarbons, and none from the oxydations of tissue. Haidenham, in 1864, arrived at a similar conclusion; and Donders was likewise of opinion that tissue transformation would not account for all the force of the animal body.

The hypothesis of Liebig has been further shaken by the investigations of Dr. Edward Smith, who has shown that the proportions of nitrogen in the urine does not increase with exercise, although the amount of carbonic acid exhaled by the lungs does. But the most convincing proof of the fallacy of the hypothesis was furnished in 1866 by the experiments of Dr. A. Fick, the Professor of Physiology at Zurich, and Dr. J. Wislicenus, the Professor of Chemistry.

On the 29th of August of that year they prepared themselves for an ascent of the Faulhorn, one of the Bernese Alps, which rises 6417 feet above the Lake of Brientz. For seventeen hours before the journey, they took nothing in the way of solid food but cakes composed of starch, fat, and sugar; and on the following morning, at half-past five o'clock, they began the ascent, choosing the steepest of the practicable paths from the little village of Iseltwald on the Lake of Brientz. At twenty minutes past one in the afternoon their journey was accomplished without fatigue, and from that hour to seven in the evening they remained at rest in the hotel at the top of the mountain. During the whole of that time (a period of thirty-one hours) they took no other food but the non-nitrogenous biscuits; but at seven o'clock they had a plentiful meal of meat, &c.

The urine was collected at three intervals, namely :—

1st. From 6 o'clock P.M. of the 29th to 5 A.M. of the 30th; and this they called the *night urine.*

2nd. From 5 A.M. of the 30th to 1.20 P.M.; and this they called the *work urine.*

3rd. From 1.20 P.M. to 7 P.M.; and this they called the *after-work urine.*

4th. From 7 P.M. on the 30th to the morning of the 31st; and this they called the *night urine.*

All these were analysed for nitrogen, and the results were as follows :—

	Grains of Nitrogen Secreted by Fick.		Wislicenus.	
1st. Night urine ...	106·7		103·1	
2nd. Work urine ...	51·1	88·6	48·3	85·6
3rd. After work urine ...	37·5		37·3	
4th. Night urine ...	74·3		82·5	

So that not only were they able to perform the work without a nitrogenous diet, but the quantity of nitrogen excreted was less during the work, than before or after. Even calculated at the hourly rate of excretion, it stands thus :—

	Grains of Nitrogen Hourly excreted. Fick.	Wislicenus.
During 1st night ...	9·72	9·41
During time of work ...	6·33	6·02
During rest after work ...	6·17	6·17
During 2nd night after work	6·94	7·87

The work which they had performed was estimated thus :—Fick weighed 145·5 lbs. avoirdupois, and Wislicenus 167·5 lbs.; and as they had ascended 6417·5 feet, it is clear that Fick had raised 933,746lbs. one foot high (145·5 × 6417·5), and Wislicenus 1,074,931lbs. (167·5 × 6417·5); so that for an expenditure of muscular tissue, represented in the one case by 88·6 grains of nitrogen, and in the other by 85·6 grains, the foregoing amounts of work had been done. Now, as 1 of nitrogen represents 6·4 of dry muscular tissue, it is evident that Fick had consumed 567 grains of muscle, and Wislicenus 547·8 grains.

At the time of the experiment, the thermotic and mechanical powers of these proportions of flesh were not accurately known, but they have been since determined in a very careful manner by Dr. Frankland, who finds that when pure dry lean of beef, albumen, and urea are completely oxydised in a proper apparatus, they develop the following amounts of heat and mechanical force :—

	Lbs. of water raised 1° Faht.	Lbs. lifted one foot high.
10 grains of pure dry beef ...	13·1	10,083
" " " albumen ...	12·8	9,878
" " " urea ...	0·6	436

In considering the mechanical power of muscular tissue, it must be remembered that it is never completely oxydised in the animal body, but is changed into carbonic acid, water, and about one-third of its weight of urea, so that the potential energy of muscle is not so great as in the preceding results. Calculated, indeed, according to the proportions of urea formed, the tissues of Fick and Wislicenus were capable of the following amount of physiological energy :—

	Fick.	Wislicenus.
Quantity of muscle consumed,	567·0 grs.	547·8 grs.
Actual energy if fully burnt,	571,706 ft.-lbs.	552,347 ft.-lbs.
Available energy, deducting the urea,	563,466 ft.-lbs.	544,386 ft.-lbs.
Work actually done, ...	933,746 ft.-lbs.	1,074,931 ft.-lbs.

So that, in the case of Fick, 370,280 foot-pounds of work, and, in the other, 530,545 foot-pounds are unaccounted for. But this is not all, for, besides the mere labour of ascending the mountain, there were the movements of respiration, and the beating of the heart, and other motor actions, to be added to the work actually done.

Now each beat of the heart is estimated as equal to a lift of 4·61lbs. one foot high ; and it is considered from Donder's well-known investigations that the work of an inspiration is nearly the same—namely, 4·54lbs. a foot high. Fick says that during the ascent his pulse beat at the average rate of 120 a minute, and his respirations were 25. The beating of his heart, therefore, during the 5½ hours actually taken in the ascent was equal to 182,556 lbs. lifted a foot high ; and the respiration to 37,455 lbs. If the internal labour, or, as it may be called, the *opus vitale* of Wislicenus was in proportion to his bodily weight, as compared with Fick's—that is, as 7 to 6, then the ascertainable work done, was to the power of the muscle consumed as follows :—

	Fick.	Wislicenus.
Work of ascending the mountain,	933,746 ft-lbs.	1,074,931 ft.-lbs.
Work of circulation, ...	182,556 „	212,982 „
Work of respiration, ...	37,455 „	43,698 „
Total ascertainable work,	1,153,757 „	1,331,611 „
Actual energy of the consumed muscle,	563,466 „	544,386 „
Energy unaccounted for,	590,291 „	787,225 „

From which it appears that taking only the three factors of ascertainable work—namely, external labour, circulation and respiration, and disregarding other unascertainable motor actions of the body, which are estimated by many as greater than all the rest, the work actually performed exceeds the energy of the oxydized muscle by more than as much again.

(To be continued.)

LECTURES ON VENEREAL DISEASES

DELIVERED IN

DR. STEEVENS' HOSPITAL.

LECTURE II.

By ROBERT McDONNELL, M.D., F.R.S.,

ONE OF THE SURGEONS TO STEEVENS' HOSPITAL.

(Continued from page 154.)

RICORD'S division is anatomico-chronological. He takes into account not only the time at which certain symptoms appear, but likewise considerations furnished by the state and physiological relation of the local affections. He holds—although in this respect his opinions are of late somewhat modified—"that the primary affection alone is contagious ; that the secondary symptoms are not contagious but hereditary," and lastly, "that the tertiary symptoms are neither contagious nor hereditary, but that they predispose to scrofula."

German authorities do not adopt the classification of Ricord. Bäerensprung, of Berlin, looks at the question in an anatomico-pathological point of view. He admits syphilis to have a period of hyperæmia and a period of tubercle. Secondary syphilis, according to him, manifests itself by inflammations, limited to the superficial layer of the corium (macula and scales), and hypertrophy, more or less considerable, of the papilla; papulæ and condylomata, and ulcerations, having a condylomatous character. Affections of the iris, the testicle, the liver, the bones, ulcerations which destroy the tissues deeply, are ranged by him among the tertiary symptoms. Sigmund, of Vienna, adopts a division purely chronological. Virchow, as a pathological anatomist, classes the symptoms of constitutional syphilis into two groups. One of these has a passive or negative character—marasmus, visceral degenerations ; the other embraces the active phenomena—various inflammations. Lancereaux's division is simple and eminently practical:—

1st. The period of incubation (from the day of infection to the appearance of the chancre.)

2nd. The period of the local eruption (during the existence of the chancre.)

3rd. The period of the constitutional eruption (during the time the secondary symptoms exist.)

4th. The period of gummy productions (the time of the tertiary and quaternary symptoms of other writers.)

For clinical purposes the arrangement given by Diday of the successive phases which syphilis undergoes in its evolution is, I think, the simplest and the best. According to him, syphilis, when not hereditary, presents eight features worthy of careful scrutiny, provided the investigation of them is within our reach :—

1st. The contaminating cause.
2nd. The period of incubation.
3rd. The initial lesion (the chancre itself.)
4th. The second incubation.
5th. The prodromata.
6th. The first evolution of constitutional symptoms.
7th. The glandular affections.
8th. The successive relays of eruptions and other symptoms, often, but improperly, called relapses.

It is by a careful analysis of the symptoms which may be grouped under these eight heads, that we may arrive at a tolerably accurate conclusion with regard to the severity of the attack of syphilis, under which any patient may be suffering. It requires but a small experience to see that syphilis, like all other diseases of the kind, presents itself to us sometimes in a mild, sometimes in a severe form. The most important thing which science can hope to do in the treatment of this formidable complaint is to detect and lay down with precision the symptoms by which we may be able to predict that the complaint is about to run a mild or a severe course ; whether, in short, we can afford to allow the work to be executed by nature, with little or no help, or whether it would be necessary for us to step in and use remedies, which, although useful in one way, are certainly injurious in another ; to learn, in fact, how long we may stand by, watching the spontaneous evolution of the disease, and skilfully to determine the moment when it may be necessary for us to have recourse to those measures which correspond to the ergot, the forceps, or the cephalotribe, in the hands of the accoucheur.

The celebrated Astruc, in the end of his remarkable work on "Venereal Disease," gives an interesting account of the methods of cure used by the Chinese ; he says they have two modes of treatment, one which drives out the disease gradually by gentle sweats ; the other which takes it by storm. The latter is accomplished by mercury, or "*kiu-fen*" in the Chinese language. This is exactly what requires good generalship on the part of the practitioner, viz.—to determine the kind of case in which mild measures will be successful, or that in which he must fall back on his storming party—his "forlorn hope."

It would be foreign from my purpose to enter into any discussion as to the causes which make syphilis mild in one person, severe in another. The truth is, we know very little about this; but the fact is so. The "vérole faible," and the "vérole forte" of Diday, which you may translate as you please, the mild and inveterate, or the benign and the malignant syphilis are met with in practice ; and this is, after all, the best division of the subject for clinical purposes; it is in fact the division into syphilis, which is curable by simple rational hygienic measures, and that which requires mercury.

I consider it all nonsense to call these syphilis and syphiloid, syphilis and pseudo-syphilis. They are one and the same disease, differing in intensity, as other diseases of the same kind differ in intensity, and needing different treatment according to these differences. It is in the highest degree unphilosophical to make distinctions where no real distinctions exist.

The first great step towards proving that syphilis is a

true toxæmic disease, and therefore one capable of self-cure, was made by Carmichael.

Mr. Rose, of the Coldstream Guards, followed up what he had begun. He had a field for research among the soldiers of his regiment, which offered him a means of obtaining more accurate results than most persons in civil practice can hope to obtain. By direct observation he proved that all primary syphilitic affections could be cured without mercury, and that the secondary lesions which followed also in time, gave way to mild and simple treatment without mercury. "In my opinion," says Sir William Lawrence, "this is the most important step that has been taken towards understanding the nature and treatment of the venereal disease, and I should place the truth thus"—originating with Carmichael, and "established by Mr. Rose, far beyond any of the speculations contained even in the work of John Hunter." The clear-sighted Graves, that great and philosophic physician, gave its full value to this truth. "Mr. Carmichael, of Dublin," he says, "was the first who materially improved this important practical branch of our profession, and taught, in a clear and scientific manner, when mercury ought, or ought not, to be exhibited."

The slowness with which practitioners have come to see in syphilis a disease not essentially different from other toxæmic maladies; the tenacity with which, even to the present hour, some cling to a mercurial treatment in all syphilitic cases, are due, in a great degree, to the old, but erroneous, idea to which I alluded in my former lecture—viz., that syphilis is a disease with an unconquerable tendency always to go on from bad to worse, unless checked by the specific action of mercury, which has been supposed to destroy the venereal poison as an alkali neutralises an acid.

Carmichael fell into the error of believing in the plurality of the syphilitic poisons, he attempted to show that there were several distinct kinds of primary ulcers, each followed by its peculiar set of secondary symptoms. He conceived that in the case of each distinct primary sore, there was a distinct poison—a germ, or seed, put into the soil; that we had, as I may say, the oats sore, the wheat sore, the barley sore, and the rye sore, each bearing in time its own crop. He thus looked at the papular, the pustular, the scaly, and the rupial eruptions as the results of different poisons. Experience has not supported this view; the different forms of eruption are due to the soil, not to the seed. There were many who could see Carmichael's error, and ridicule it, who failed to catch the fundamental truth which ran through his observations. I ask, what was Carmichael's practice? In practice he separated the sheep from the goats—the cases which need mercury from those that do not—the cases, as I may say, of natural labour from those requiring instrumental interference. This truth, "éclate dans l'œuvre entière de Carmichael ce profond observateur si méconnu si travesti." Diday gives merit to whom merit is due, and I, gentlemen, preach to you the truth I learned from my first master, and I preach it to you with all the earnestness which arises from conviction of its truth.

Although I admit that we at present know no remedy which exercises so great an influence over syphilis as mercury, yet, I very confidently affirm that the majority of the cases which come before you in practice, may be cured without taking one single grain of it, and in after years they will be healthier, haler men, than if they had been treated by mercury.

But some one of you says, "if mercury is the most powerful remedy against syphilis, why not use it in the milder as well as in the severer cases; what harm does it do?"

This is a question which would be answered very differently by different practitioners; some assure you that mercury is a tonic, that men thrive and fatten on it; others tell you that it is an infernal agent to be avoided, as death or sin, that it is a source of disease worse than that it is intended to remedy.

Here again, gentlemen, although I venture to give you my own views, I do not ask you to adopt them. Do not blindly swallow my assertions, or those of any one else. Keep your eyes open: observe and note results for yourselves. You stand exactly where I, myself, did 15 or 20 years ago. You halt between two opinions. You stand as I, myself, did, to use a homely comparison, like the ass between the two bundles of hay—you know not which to turn to.

That mercury is a very powerful remedial agent, I do not question: but it is potent for evil as well as for good: it is as a two-edged sword, while it cuts the disease at the one side, it cuts at the constitution on the other. What the knife is in surgical practice, what the crotchet and the perforator are to the accoucheur, mercury is as a therapeutic agent. It should never be administered without duly considering whether the injury which it inflicts on the constitution may be fairly regarded as compensated for, by the benefit which is likely to result.

The greater ills said to arise from the use of mercurials have been, I think, exaggerated. At least, as these preparations are generally exhibited in the present day, I have rarely seen palsy, caries, madness, &c., as a consequence fairly traceable to this cause. An impartial consideration of the reports of the diseases met with among the workmen employed in mercury mines (at Idria and elsewhere), as well as among tradesmen (mirror-makers, gilders, &c.), who are exposed to mercurial vapours, does not lead to the conclusion that these very formidable consequences of mercurial poisoning are so common as some would have us to believe.

The minor ills arising from the use of mercurials meet us at every turn. Cases like the following are of almost daily occurrence:—

A young man, as a boy the healthiest of a very healthy family, met with a severe injury of the eye—according to a practice happily less frequent than it used to be, he was kept for some weeks in a dark room and mercurialized. Years afterwards he is the least robust of his family. He is sensitive to changes in the weather; before he is up in the morning, he knows from what direction the wind blows. By slight irregularities of diet dyspepsia is induced; the white of the eye is jaundiced and the urine loaded with lithates and with bile. In such cases the gums often recede from the teeth, neuralgic and rheumatoid pains pester the patient. He is a weaker vessel than he was before—convalescence from slight illness is slow—such individuals are more a prey than their neighbours to that slighter form of melancholia which we commonly call "the blues." The use of mercurials for any considerable time, transforms a moderately strong man into what we ordinarily call a miserable devil. It makes him hippish and hypochondriacal, and gives him a greater proclivity to disease than others. In short, "the thousand natural shocks that flesh is heir to,"—even to the most robust of us—become, in his case, multiplied into ten thousand.

Mankind in the aggregate suffers more annoyance from such creatures as mosquitoes, gnats and midges, than from the depredations of the lion and the tiger; so the minor ills arising from mercury in their aggregate, bear harder on mankind than the more formidable but rarer affections of a grave character which are traced to it.

Such, gentlemen, are my views, yet I know that you will meet some who have enjoyed large opportunities of practice, and yet have not recognised the ill effects arising from mercury; they say, it does no harm and may do good; and so it becomes taught as a principle, (I do not now speak of the treatment of syphilis), that when you are in doubt as to an obscure affection, you should give mercury: it is said—fire into the bush, you may have the good luck to shoot the hare which perchance is lurking in it and you do the bush no harm.

Against such a principle I cannot speak too strongly—to be in doubt is to be in ignorance—and better far admit one's ignorance than blindly have recourse to a remedy which the experience of mankind admits to be anything

but harmless. It is a principle which inculcates that you are to inflict upon your patient a very certain injury, with a very slender chance of doing him any good. It is a principle against which it may seem to some of you almost ridiculous to have to raise one's voice in the present day; yet, I assure you, it is one even still but too generally acted upon.

To return, however, to the subject of syphilis, I have, I trust, explained to you the apparent paradox: that while I admit that no remedy exercises such an influence over this disease as mercury, I should recommend you to have recourse to it in practice as rarely as possible.

There are in No. 2 Ward, at the present moment, four patients—

Peter K.,	. .	18 years of age.
Michael B.,	. .	25 „ „
Michael D.,	. .	22 „ „
Matthew M'D.,	.	58 „ „

suffering from secondary venereal symptoms, each presenting characteristic eruptions, &c. These patients have been under my care from the first—that is, these four have not, as some others, been treated mercurially by any other practitioner before admission to this hospital. Of these four, one is taking, and one has used, mercurials; two have not, and, I hope, never need take any.

To point out to you the principles which guide me in making this important difference in treatment, shall be the object of my next lecture.

In conclusion, I would observe that in the wards of an hospital like this, you meet with a larger number of cases requiring the use of mercury, as a remedial agent, than you will meet with in ordinary practice; and for this very simple reason—the slighter cases, the cases of what Diday calls "vérole faible," do not require to come into hospital for treatment. The bulk of the cases of syphilis which you see here are severe, or malignant syphilis.

During ten years, while I was Medical Superintendent of the Mountjoy Convict Prison, I met with 54 cases of syphilis. This is a small array when compared with the hundreds and thousands which figure in the statistics of some. The power of accurate observation within prison walls, the certainty and precision of the facts, the removal of many of the disturbing influences which confound results and observations made on ordinary patients; above all, the power of watching for years the undisturbed progress of the case, give, however, a great scientific value to observations made within the precincts of a convict prison. Of my 54 cases, 13 were from the first under my own care, never having been interfered with by any treatment until after their committal to prison. Of these 13 two only appeared to need mercurial treatment; the rest got well under that simple, rational, hygienic treatment, which can be so well carried out within a prison, where habits of dissipation are at an end, and time is no object.

Original Communications.

PHTHISIS PULMONALIS AND ITS TREATMENT BY "PANCREATIC EMULSION OF FAT."

By R. J. KINKEAD, A.B., L.M. T.C.D., L.R.C.S.I., Etc.

In order to treat phthisis pulmonalis with any hope of being successful, it is absolutely necessary to consider carefully as much as we know of the pathology of the disease, the exciting and predisposing causes, and to inquire into the nature of what we call the tuberculous deposit.

It is only by so doing that we can act from knowledge like men endowed with reason, and not by guess-work and routine practice, in many instances sacrificing our patient's lives, and bringing disgrace on our profession.

It is this knowledge which enables us, from amongst the multitude of remedies offered for our use, to choose those likely to prove beneficial, and to reject the useless and injurious. This knowledge enables us also to avoid the too common mistake of thinking that a medicine which in some cases does good, must be a specific, and of itself and by itself, able to cure phthisis, and so neglect that combination of remedies which, in this disease, is most essential to guide it to a successful issue.

Our knowledge of the constitution of tubercle is anything but satisfactory. Two opinions are chiefly supported by pathologists, one class affirming that tubercle is an exudation essentially morbid, the other, that it is merely a retrograde metamorphosis of pre-existing structures, either natural or morbid.

One of its essential characters is that, however deposited, it is incapable of development, but on the contrary, has a constant tendency to degenerate. Tubercles are either grey or yellow; the grey are tough, soft, of a pearl-grey colour, have a certain degree of organisation, being composed of round, oval, or triangular-shaped bodies imbedded in a basis substance, and are soluble in liquor potassæ.

The yellow appear to be a degenerated, and more especially a fatty degenerated, form of the grey.

Tubercle is generally produced without inflammation, as implying pain, redness, swelling, and the production of lymph or pus. The question now arises as to the origin of tubercle. What are its exciting and predisposing causes? The exciting causes are, generally speaking, cold, and breathing an atmosphere loaded with irritating particles.

Our knowledge of the predisposing causes is not at all so clear. What we do know seems to be something like the following—That it is an essentially constitutional disease. Whether local irritation, such as living in an atmosphere loaded with minute atoms of organic matter, can occasion the local development of tubercle without the constitutional tendency being present; whether "the knife-grinder's rot," the so-called cases of "consumption" in flax-scutchers, &c., are really cases of tubercular phthisis, or merely of hectic fever, induced by numerous spots of circumscribed inflammation, running on into abscess, or causing excessive purulent expectoration from inflamed bronchi, occasioned by the lodgment of minute particles of extraneous matters in the lungs, is yet to be solved. But be this as it may, the constitutional nature of tubercle, whether developed in the head, lungs, or mesentery, is one of the best-established facts in medicine. At the head of these constitutional predisposing causes stands hereditary taint, and then comes whatever tends to bring the system into a state of deficient nutrition.

In this state of the system, in which tubercle is likely to be developed, we cannot say that the blood is in fault so much as the pabulum, which ministers to the nutrition of the body, through the blood, which impoverishes the blood, and, as a consequence, brings the tissues of the body to an impoverished condition likewise. In this state the blood becomes albuminous, and white corpuscles become increased.

The gastric and intestinal acids become greatly augmented, more than neutralising the alkaline secretions of the saliva and pancreatic juice, and so render them incapable of preparing fatty matters for absorption, and under certain circumstances render the albuminous constituents of the food more soluble. Hence more albuminous than oleaginous elements enter the blood, and cause the albuminous character of the blood, which, infiltrating the tissues, may in some instances be changed by coagulation into grey tubercle.

It is a certain fact that in most cases a low state of the system, accompanied by a poor state of the blood, is, if not a certain, at least a most probable predisposing cause, and in all cases tubercular phthisis is accompanied by this cachectic state of the body.

In considering the progress of tubercle, the tendency to degenerate which characterises it is an example of what has not inaptly been called the "vis naturæ medicatrix."

Grey tubercle degenerate into yellow, and the yellow to a puriform mass, which sometimes excites just sufficient inflammation to cause its own expulsion, leaving a cavity behind which (if there are no more tubercles or cavities in

the neighbourhood) contracts. The walls pucker in, and finally become obliterated, or the watery particles may be absorbed, the earthy constituents concrete, and the mass be converted into a hard chalky substance, principally consisting of phosphate and carbonate of lime, which is sometimes coughed up, or covered by a false membrane, may remain for years harmless in the lungs.

Cases of phthisis pulmonalis may, in my opinion, be divided into three classes :—

I. Cases in which tubercles are developed rapidly in great numbers, and of small size (milliary), occupying, perhaps, the greater portion of the lungs (tubercular infiltration of Baillie), accompanied by inflammation, and running a rapid course.

II. Cases in which tubercles are confined to one portion of the lungs, but are constant there, appearing for an uncertain time neither to get better or worse, but occasioning a certain amount of ill health—throat or stomach symptoms being most frequently complained of.

III. Cases in which the tubercles are deposited in crops in limited portions of the lungs, giving rise to febrile exacerbations, and intervals of health, according as the tubercle is deposited and got rid of by expectoration or concretion.

In the first class we can do little or nothing. In the second, and more especially in the third, class we can do much.

On being "called in" to a case of phthisis our efforts must first be directed to subdue any inflammation present, to allay any irritation in the lungs which would encourage the growth of tubercle ; secondly, we must endeavour to procure the elimination or absorption of the tubercular matter ; and, thirdly, we must strive to prevent the redeposition of tubercles.

Our treatment of the inflammatory attacks must be guided by the symptoms and nature of each case. The remedies that would produce the best effects in one might be most injurious in another.

The treatment likely to produce the elimination of tubercles is almost identical with that necessary to prevent their redisposition, and constitutes the, so to speak, "specific" treatment of phthisis, and may, in a word, be said to consist of putting into and keeping the body in as perfect a state of health as possible.

I purposely omit to speak of the efficacy of climate, although I believe that in most cases a judiciously chosen climate is absolutely essential to a perfect and permanent recovery. The other indications will be best obtained by procuring the assimilation of fats which supply respiratory food to the lungs and help to enrich the blood.

At the head of oleaginous preparations stands cod-liver oil, of which it is not stating too much to say "that its use has, to some extent, removed tubercular consumption from the list of incurable diseases."

The chief obstacles to its administration are the disagreeable taste, and its occasioning sickness. The class-books teem with recipes to obviate the former ; the latter, I believe, is occasioned, not by any intrinsic quality of the oil but by that excessive acidity of the gastric and intestinal secretions so characteristic of scrofulous cachexia, as to have gained the name of "strumous dyspepsia." This acidity may, in many instances, be overcome by combining alkalies with the oil. But even this method will fail in some cases, and the stomach still continue to reject the oil.

In these cases, and in those in which the repugnance to the taste cannot be overcome, I have found "pancreatic emulsion of fat" a most valuable agent. The office of the pancreatic juice in the body (it has alkaline properties) is to emulsify the fats, and render them fit for assimilation by the lacteals. The acid state of the gastro-intestinal tract in phthisical patients neutralises the action of the pancreatic secretion, and in some cases causes an excess of acidity. Now, pancreatic emulsion offers to the stomach the most easily digested fat (mutton suet) prepared for absorption by the very juice which disease has neutralised. So that, in one case, we have pancreatic juice neutralised by acid, and pancreatic juice and fat free to act, and, therefore, the fat easily absorbed ; and where the acid is in excess by the addition of an alkali, we have pancreatic juice and alkali neutralising acid, and pancreatic juice and fat free to act. But what is perhaps its most important action, is the educating the stomach to receive and digest oils, for, after the emulsion has been administered for some time, it will be found that cod-liver oil will agree in those cases in which before it did not.

The following case is not to be considered as a complete observation, owing to my unavoidable absence from home during a portion of the patient's illness ; nor do I think I am entitled to state that her recovery was entirely owing to the use of pancreatic emulsion ; neither do I say that her recovery will be permanent. But I do say that, from the circumstances of the case, I am entitled to argue that the emulsion aided, in a great measure, her restoration to health—and that, although the disease may recur, yet a rescue from immediate death and alleviation of suffering, if occasioned by a remedy, are sufficient, even if its powers are limited to few cases, to place that remedy high in the list of our most valued ones. But, I believe, that more extensive experience will prove what theory, and the little experience we now have, indicate, that pancreatic emulsion, supplying to the system as it does (what it most wants in scrofulous cachexia), a very large amount of nutriment with the least amount of digestive labour, and in a form most easily assimilated, will, when combined with proper treatment, and judiciously followed up by dietetic and hygienic rules, enable us to assist nature to cure a much larger proportion of phthisical cases.

Towards the end of August, 1867, I was "called in" to attend C. G., æt. 19, unmarried, by occupation a laundress, suffering from a severe cough of about three weeks' duration.

She had, for a girl of her rank of life, a peculiarly fair delicate complexion. The veins could be clearly seen ramifying under the skin ; upper lip slightly strumous ; eyelashes very long ; and hair of a reddish brown colour.

Her father and three brothers had died of acute phthisis.

Up to the period of her present illness her health had been good. At the time I first saw her, she presented most prominently the symptoms of inflammation of the lungs, but the breathing was more hurried and difficult than the amount and violence of the inflammation (confined to a portion of base of left lung) would account for. On a more extensive examination, I found the right side perfectly healthy, but there was slight dulness under left clavicle, and in the supra scapular region.

Expiration and inspiration were equal, the latter, too, was interrupted.

The pulse was rapid and weak.

Blisters ; small doses of tartar emetic, and the free administration of wine and nourishment, reduced the inflammation ; the respiratory murmur returned (save in the subclavicular and supra-spinous regions), and she was enabled to return to her usual occupations. From this time (Sept. 5) till sent for on Sept. 29, I did not see her.

I found her complaining of pain in left side (pleuritic stitches) ; short hacking cough ; night perspiration ; respiration rapid ; pulse 90, weak ; expectoration glairy and frothy, and containing bodies like grains of rice ; dulness increased in extent, reaching from left clavicle to upper margin of fifth rib ; bruit in left subclavian ; face pale ; complains of weakness. Ordered potass iodidi, gr. xxxii., liq. ferri iodidi, ʒiii., ol. morrhuæ, ʒviiss., a dessert spoonful three times a day ; wine, jellies, and nourishment were freely administered.

On the 5th of October, she got an acid and iron mixture, which restrained for a short period the perspiration, but she rapidly got worse ; great wasting set in ; lips became ex-sanguid ; dulness increased ; expectoration became nummular and purulent ; respiration difficult, and I detected pectoriloqui, and on one day metallic tinkling. The stomach became so irritable that it was with difficulty that it could be made to retain even a small portion of milk. The perspirations now became excessive ; the pain

in the side was constant and agonising, and she sunk so low that I expected her death daily. She complained so of want of rest from the pain and cough, that I gave her, as she presented no symptoms of deficient aeration of her blood, ℞ liq. morphiæ hcl., ♏30, acid hydrocyan. dil. gtt. i., liq. bismuthi (Schacht) f. ʒi., emuls. amygd., f. ℥i., omni nocte, s.; this gave some relief.

On the 14th October I commenced the pancreatic emulsion, in two teaspoonful doses, two hours after dinner and supper, but on the second day I had to diminish the dose to one and a-half spoonful, owing to its occasioning sickness. After this, I can only describe its effect by saying it seemed "to work like a charm." The cough grew less, the drenching night perspiration diminished; the respiration grew so much easier that the patient was able to lie down at night, which for some time previous had been impossible, owing to the difficulty of breathing it occasioned; the pains grew so much easier that she was able to dispense with the anodyne draught at night; the pulse sank gradually from 130 to 70, and, at the same time, grew full and strong. She increased in weight and grew stout, and her strength returned by degrees.

Now, the mere fact that after taking the emulsion, she so rapidly recovered, would, by itself, be very insufficient evidence as to the efficacy of that remedy; it would be merely a "post hoc ergo propter hoc" assertion, and, consequently, of very little weight. But this fact, purposely omitted from the report of the case, changes the nature of the assertion, and proves that the emulsion was, at least, the most important agent in effecting her recovery. Two bottles of the emulsion were first sent down from Dublin. Whilst taking these the improvement in the patient's health was most marked; before the second bottle was finished, a fresh supply was written for, but owing to some unaccountable delay, it did not arrive till 9 or 10 days after the first supply was exhausted. During this interval, although the other treatment was continued, she sensibly fell back. The cough, pain in sides, and perspirations became worse, and she felt weak and desponding. On recommencing the emulsion, she began again to amend, and continued steadily to recover.

In a chronic case, the cough and breathing grew easier, and the perspirations ceased during the use of the emulsion. In both these cases, cod-liver oil, which had hitherto been persistently rejected, was retained by the stomach after the emulsion had been administered for some time.

CASE OF GENERAL PARALYSIS SUBSEQUENT TO CHOLERA.

By WALTER G. SMITH, M.B.T.C.D.

(Read before the Medical Society of the College of Physicians, Wednesday, January 15, 1868.)

The object of recording rare or exceptional cases in medicine or surgery, may be assumed to be twofold; either the writer wishes to publish an individual case, as an instance of an uncommon form or unusual sequela of disease, or he is desirous of illustrating the beneficial effects of a particular course of treatment, so far as any inference can be drawn from a solitary example. It is on both these grounds that I submit the notes of the following case to the Society this evening, and I may be permitted to say that I have not been able to meet with a similar case on record.

On the 25th November, 1866, I was called to see, in the absence of my father, Mr. J. W., aged 29 years, and found him labouring under diarrhœa.

Next day, my father visited him, and he was apparently doing well, but early the following morning we were hastily summoned to his bedside—profuse vomiting and purging having occurred during the night.

He was immediately removed to a private ward in Sir P. Dun's Hospital, and on his way to the hospital he vomited and became very weak. He remained there for nearly three weeks under Dr. Bank's care, and passed through a severe attack of cholera. The stage of collapse was particularly well-marked, and he suffered from troublesome and long-continued hiccup, which it was found difficult to control by any remedies, and he also experienced some difficulty in swallowing, attended with spasms across the chest, towards the close of the attack.*

He left hospital on the 17th of December, in good spirits, though greatly prostrated, and went to his father's place in the King's County. He did not long enjoy the change of air before he began to feel some numbness in the lips, mouth, and tongue, which was especially remarkable while in the act of drinking.

In the second week of January, *i.e.*, about three weeks after leaving hospital, his attention was attracted by his lower extremities failing in strength.

The first decided warning he received of impending mischief, was an inability to walk steadily. He staggered so visibly, that he was ashamed to walk abroad, as the people used to gaze at him, supposing that he was tipsy. After vainly striving against this weakness for a time, he was obliged to make use of a stick, and ultimately he could not stand at all without assistance.

He returned to Dublin on the 20th January, 1867, for medical advice. When I first saw him in town with my father, he tottered greatly, but was still able to stand upright, with his feet together, and his eyes shut, though with an inclination to fall forwards.

Long before the arms were affected, he perceived that sensibility was greatly diminished in the calves of the legs, so much so that he was scarcely conscious of feeling the weight of one of them when in the crossed position. In the after history of the case, it was remarked that washing his feet with tepid water occasioned such a sensation of tickling in the part, as was actually painful to bear. This numbness gradually extended, and was shortly followed by numbness of the upper extremities, commencing in the fingers, which, at the same time, became spasmodically contracted. When he attempted to lay hold of any object, his hand was suddenly flexed, and he could not seize it unless he carefully watched the hand, and controlled its movements with the eye. This tendency to contraction was first noticed in the ring finger of the left hand.

During the next week he rapidly lost power over all the extremities, became so helpless that he was unable to turn in bed, and if his feet were crossed, he was quite incapable of separating them.

His condition at that time was really distressing; completely paralysed, he passed some days in an almost vegetative existence; motionless, not even possessing strength enough to draw the bed-clothes over himself, yet with his mind clear and active. He was much annoyed with severe tensive pain in the feet, which was completely relieved by friction, and the slightest movement or exertion caused intense pain and distress. At no time were the involuntary muscles seriously affected, though for two days, after he came up to town, he partially lost control over the rectum and retained the fæces with difficulty. He could always command the functions of the bladder, but the sensibility of the urethra was evidently diminished at one period, for he could scarcely feel the contact of the urine with the mucous membrane as it passed out of the body.

His urine, I regret to say, was not examined.

One of the most remarkable points connected with this case is the following:—

During a period of about ten weeks, for a portion of almost every day, he was unable to introduce the smallest particle, solid or fluid, into the stomach. Whatever he swallowed passed readily down the œsophagus, but near its termination seemed to be suddenly arrested by an impediment in, or constriction of, the passage, through which not an atom found its way. A few minutes after deglutition, part of the food regurgitated into the mouth, the act being at-

* Mr. E. Collins, Med. Sch., was the resident pupil at the time, and took notes of the case.

tended with slight hiccup, and in a short time the whole was returned.

At this juncture he suffered from soreness of the throat, and for three weeks from acute pain across the chest whenever he attempted to swallow fluids, particularly on the left side under the scapula, thence passing into the arm, and leaving it numb and powerless for a few minutes.

A curious symptom presented itself coincident with the œsophageal obstruction, viz. spontaneous salivation.

Every day for many weeks, a copious secretion of thick ropy saliva took place, and he commonly ejected four large cupfuls in the twenty-four hours.

It must be borne in mind, that at no time was mercury, iodide of potassium, arsenic, or other specific sialogogue administered; neither was there any patent cause of irritation in the neighbourhood of the salivary glands, nor in the teeth or gums.

It was observed that the spasmodic closure of the œsophagus lasted, on a average, about three hours, but, on one occasion, in the month of February, not a particle of food, solid or fluid, could be introduced into the stomach for a period of sixty-eight hours, and we should have been forced to employ nutritious enemata to support his strength, had not this untoward symptom been relieved by the application of a large blister over the epigastrium.

I shall now briefly glance at the line of treatment adopted. In the earlier part of his stay in town, he was put on a combination of ergot of rye, with extract of belladonna.

This not proving satisfactory, extract of nux vomica was exhibited for some time, and pushed till muscular twitchings were produced but under both these methods of treatment he was sinking into a more helpless condition.

I have alluded to the striking manner in which the incapability of the œsophagus to permit the passage of subtances towards the stomach was completely dissipated, when it had continued for nearly three days, by the stimulus of a blister to the epigastrium.

Had I been aware of it at the time, I should have tried the effect of sipping orange juice for the relief of the salivation, a practice which has been found successful in the excessive secretion attendant on œsophagism.

Finding the above means unsuccessful it was decided, at my father's suggestion, to have recourse to electricity, and the first trial of it was made on the 25th of last February.

The apparatus I used throughout the case was constructed by Messrs. Elliott of London.

It consists of a single Smee's element, the amalgamated zinc plates and the central platinised silver lamina, being about 4½ by 1½ inches each, thus exposing a surface of nearly seven square inches. They are excited by dilute sulphuric acid; one part of oil of vitrol to eight parts of water. The poles of the battery are readily put into connection with the thick primary or inducing wire of an upright induction coil, and the electrodes can be so arranged that the operator may collect at pleasure, either the extra current developed by the mutual action of the spirals of the primary wire on each other, or the more intense current induced in the fine secondary wire, or, if he wishes, can call into action a combination of these two currents.

The intensity of the induction stream is increased by the presence of a bundle of soft iron wires, in the centre of the bobbin, while the influence of this central temporary magnet is regulated by withdrawing more or less of a copper envelope which closely surrounds these wires.

The necessary interruption of the battery current is secured by an ordinary trembler or rheotome, and the rapidity of the intermissions is governed by a screw which alters the distance of the trembler, from the central core of soft iron. The whole fits into a box 7 inches in height, 6·5 inches in width, by 4 inches in depth, portability and lightness being specially aimed at in its construction.

The slight inconvenience arising from the necessity of using acid with such a machine, as compared with the rotating magneto-electric machines is, I believe, far more than counterbalanced by the direct advantages resulting from the employment of a volta-electric arrangement, for

1°. The latter can be worked without an assistant for hours at a time.

2°. Its action is more uniform, and more easily regulated.

3°. The current evolved from it does not cause so much pain, or such irregular muscular contractions as the magneto-electric current.

4°. The ordinary magnetic machines are more liable to get out of order, become demagnetised after a time, and do not furnish nearly such a large quantity of electricity; and

5°. The disagreeable noise produced by the movements of the wheels and armature of soft iron contrasts unfavourably with the quiet hum of the invisible little trembler.

I began with a gentle secondary current to the right arm, and the second day after directed the faradisation to the left arm.

It would be tedious to go step by step through the details of treatment, and I shall therefore present the facts in a condensed form.

As a rule, the patient was faradised three times a week, for about ten minutes or a quarter of an hour at each sitting. At first the secondary current was alone employed, but after a time the combined primary and secondary current was brought into play, which I have always found to exercise a considerably greater influence on the motor nerves than the secondary only.

The right and left extremities were usually excited on alternate days, and the total number of applications, extending over six weeks, was as follows:—Lower extremities about thirteen times, right arm about twelve times, and left arm about nine times. It is right to mention that for the greater part of the time during which the treatment by electricity was pursued, he took no medicine of any description, with the exception of a few diuretic powders (soda bicarb., pot. nitr. aa. gr. v.) for the relief of some temporary œdema of the feet.

A liniment of aconite and chloroform was rubbed in along the spine for a day or two, but beyond this no internal or external medication was resorted to.

The steps towards restoration to health were encouraging, and steadily progressive.

Very shortly after the employment of the induced current the arms began to gain in strength, and in about a fortnight he could stand with a little aid, though still with a tendency to fall forwards.

Gradually and slowly he regained the power over the lower extremities, and simultaneously there was a marked increase of susceptibility to the electric influence.

It was not till a week later that he was successful in moving forwards a step or two without assistance, and with his eyes shut.

Two marks of improvement he especially noted himself, viz.: that his hands lost the yellow hue which they exhibited in the early periods of treatment, and that he no longer suffered from cold feet. The circumference of the limbs increased rapidly, and within six days the right arm had gained to the extent of three-quarters of an inch. The calves of his legs by degrees resumed their natural dimensions, and on the 27th March he felt strong enough to drive out for a short time.

As soon as he was able to write firmly the faradisation of the arms was omitted, and on the 11th of April I saw him for the last time, and learned that he had walked two and a-half miles the day previously in an hour.

Change of air and country life soon recruited his strength, and early in May he came up to town, and for two or three days was again annoyed by the spasmodic obstruction in the œsophagus, which was once more relieved by the application of a blister.

On the 3rd of December, 1867, I met him in College, looking remarkably strong and healthy. He told me that

he thought nothing of walking fourteen miles in the day, but was still frequently troubled with the resistance of the œsophagus to admit solids, so much so that he was seldom in a position to eat a hearty dinner.

We may, I consider, view this case before us as an example of paralysis consequent on blood-poisoning of the nerve-centres, or, more probably, of nervous malnutrition after the exhausting discharges of a grave attack of cholera.

Dr. Handfield Jones has shown, and Dr. Russell supports his views in some recent papers in the *Medical Times and Gazette* (October 10th, 1863, May 25th, 1867), that, of the various influences which tend to depress the functional energy of the spinal cord, some act upon the nervous tissue in common with the rest of the body, while others exert their power upon the nervous tissue exclusively, and the successful termination of Mr. W.'s case, which would come under the former head, was doubtless mainly due to the asthenia of the cord having been arrested speedily, and thus any destructive organic change anticipated, for the prognosis is favourable in proportion as appropriate treatment is adopted sufficiently early.

In similar cases, it is well to remember that the existence of a state of malnutrition will exert an unfavourable influence on the prognosis should even a small amount of organic mischief be set up.

It will, perhaps, be readily granted that a parallel may be drawn between this case, and those cases of paralysis resulting from spinal exhaustion induced by masturbation or venereal excesses.

Dr. Russell has given the details of some cases of this nature in an interesting paper in the *Medical Times and Gazette* for 1863.

The analogy may be traced in the mode of invasion, in the impairment of sensibility, in the legs being primarily affected, in the diminution of muscular irritability, and in many other particulars. But one point of difference especially is to be remarked—viz., that while in the cases related by Dr. Russell, paraplegia was the prominent symptom, the motility of the upper extremities being unimpaired in Mr. W.'s case, all the voluntary muscles were implicated, though the affection of the arms was secondary to that of the legs. Dr. Russell likewise was unable to see any benefit accrue from the continued employment of strychnia, even when the alkaloid was administered in quarter grain doses, and produced its well-known physiological effects powerfully on the paralysed limbs.

Looking back on the general history of the patient, and especially on the steadily downward tendency of all his symptoms before subjected to treatment, it would seem that this case may fairly be placed in the category of cures rather than that of recoveries.

During the whole of his stay in the country he was daily and sensibly growing worse, nor was there any decided amelioration in the symptoms till electricity was resorted to. Even granting that in many cases of paralysis, apparently resulting from toxæmia or from deficient nutrition, the prognosis is hopeful, it will at least be conceded that his progressive restoration to health was eminently assisted by the application of faradisation.

The improvement resulting from the employment of the means used was noticeable from the beginning, yet we should not be deterred from persevering in faradic treatment even when no perceptible effect is produced at first. Of this I have at present an instructive example under observation in the Adelaide Hospital.

In conclusion, I would say a few words respecting the meaning of the terms to be adopted in speaking of treatment by electricity.

By electrisation is understood the employment of static or Franklinic electricity, as produced by frictional means or accumulated on a Leyden jar.

Galvanisation implies the use of the continuous galvanic current, as evolved from a voltaic pile or battery, and faradisation expresses the local application of induced currents, whether caused by the mutual action of the spirals of a short and thick wire on each other, or by the influence of a permanent magnet, or by a current circulating through a closed wire, and which admits of being rapidly opened or completed.

It is a fitting tribute to the memory of that great philosopher who has so lately passed from among us, that his name should thus be perpetuated in that branch of science in which he was chief.

Much of the discrepancy which is so often confessedly met with in the records of electro-therapeutics is, I am convinced, traceable to the carelessness and inaccuracy of writers with reference to the form of electricity selected and the precise manner of applying it.

Dr. Althaus, in his valuable work, gives some striking examples of errors arising from this source (see p. 163 and 343). Electricity is an agent potent for evil as well as for good, according as it is directed, and though, when unadvisedly employed, it too often becomes an instrument of much mischief, yet, under judicious management, it is a tractable as well as a valuable servant, and it is especially remarkable as being one of the few potential remedies which the physician can command.

Literature.

We have on a former occasion freely acknowledged the impossibility of condensing into a brief review an adequate account of such a volume as some of the hospitals yearly issue. In order to make up for this we instituted the plan this year of briefly noting some of their more striking points, and returning at intervals to the individual papers. In this way we have, during the last two months, given full attention to the volumes of St. Bartholomew's and St. George's, though we have far from exhausted their contents. We have now before us the new volume of Guy's Hospital Reports,[1] the oldest annual of the kind, and this year as worthy as ever of the great reputation of the school. We could wish, even if the present cover is to be continued for the sake of uniformity, that on a future occasion the edges might be cut. In books which are standard works of reference, too little attention is paid to the binding. In this respect the works of the new Sydenham Society are a model which would be well worth imitating. But to our Guy's Report. Mr. Cock opens with a second case of Pharyngotomy for the removal of a foreign body impacted in the pharynx. In both the cases now recorded by the Senior Surgeon of Guy's Hospital, nourishment was able to be given by a flexible catheter prior to the operation, and afterwards the patients were sustained by nutriment freely administered both by the œsophagus tube and enemata. Mr. Hilton follows with clinical lectures delivered during the last winter session on (1) a fatal case of rupture of the left kidney, in which hæmaturia was a prominent symptom, and in which he speaks of clots of blood as aids in diagnosis. (2.) The diagnostic indications afforded by blood from the urethra, rectum, or stomach, the chief point being that a clot may destroy life as in cut-throat, or in operations about the mouth. (3.) Cases showing how a clot destined to arrest hæmorrhage may endanger life or interfere with the success of an operation. (4.) Extraneous bodies floating in the thecæ, connected with the tendons of the fingers. Long standing ulcer on a stump cured by rest. Arrest of repair in a stump, benefited by division of nerves. (5.) Simple fracture of femur followed by tetanus. Lacerated wound over knee followed by suppuration of the joint, and anchylosis of femur and tibia in a good position. It will readily be understood that these cases, with Mr. Hilton's remarks, are all particularly interesting. The materials of the lectures have been arranged for publication by Mr. Eastes, the able Surgical Registrar.

Mr. Salter, M.B., F.R.S., Dentist to the hospital, furnishes an essay on affections of the nervous system dependent on diseases of the permanent teeth, which we commend to all engaged in dental or in general practice. Then Mr. Cooper Forster details the cases in which Sir James Simpson's discovery of acupressure has been tried at Guy's.

Dr. Hicks relates forty-one cases of uterine polypi. These are sure to attract the attention of the general reader.

The next paper is a most valuable contribution on some of

1 Guy's Hospital Reports. Edited by C. Hilton Fagge, M.D., and Arthur E. Durham. Third Series. Vol. XIII. London: J. Churchill and Sons. 1868.

the affections commonly classed as nervous deafness by Mr. J. Hinton. It details at length twenty-three cases, interspersed with many valuable observations. The whole paper is written with that care and lucidity of expression, which have placed the author among our first writers, and with that practical knowledge which have given him so great authority as a practitioner.

Dr. Owen Rees relates and comments upon two cases of elephantiasis græcorum. Dr. Fagge follows on certain rare cutaneous affections. We meet again with Mr. Hilton, as contributor of a case of colotomy, in which the operation was twice repeated. Two plates illustrate this case. Dr. Taylor next gives cases and observations in medical jurisprudence. This is followed by Dr. Fagge on keloid and allied diseases—an elaborate paper of 74 pages.

We have next a still more exhaustive paper by Dr. W. Moxon, on the history of visceral syphilis, extending to 80 pages of letterpress, and illustrated by two plates, each containing three figures representing syphilitic affections of the kidney and diaphragms, and their microscopic characters.

Dr. Stevenson gives us a note on a case of melanuria. Mr. Bryant follows with his late case of splenotomy; a second contribution by Mr. Bryant is on malposition of the testicle, and here again we have two plates.

The guaiacum process for the detection of blood in medico-legal cases, and the antozone test are considered by Dr. Taylor. The dissection of a monster is the subject of the next paper, by Dr. Hicks and Mr. James Bankart, conjointly. There are three plates to this paper. Two papers follow from the pen of Mr. Birkett, the first on intestinal obstruction; the second on the operations performed in the hospital during the last ten years, for the removal of stone from the bladder. Mr. Durham adds a case of the hæmorrhagic diathesis, and Dr. Pavy, an essay on gastric erosion. The volume closes with the second series of Mr. Bader's human eye in health and disease, as seen with the ophthalmoscope, the first series having appeared in the reports for 1865. This second part is illustrated with six beautiful chromo-lithographs, showing the appearances of the optic discs of differently coloured eyes in health. We have thus enumerated the contents of this valuable volume. Twenty-two essays by the staff of Guy's Hospital could not of course be criticised in the space at our disposal for a single book. We must therefore rest content with having briefly pointed out what the work really consists of, reserving an analysis of some of the most practical papers, or an outline of some of the most striking cases for future consideration. These we shall probably digest from time to time, in the columns we devote to hospital reports, much in the same way as we have adopted with the St. George's and St. Bartholomew's volumes—a plan we are pleased to find has given universal satisfaction.

HOSPITALS AND DISPENSARIES.

The interest of medical men in hospitals, and other charitable institutions, their history, mode of management and arrangement, is sufficiently attested by the number of pamphlets and larger productions that have appeared of late years. From these it is also clear that the interest evinced by the general public is constantly growing, so that a wider circle of readers are ready to hear all about these charities, and the manner in which their defects may be remedied. This is undoubtedly a great advantage, for the larger the number who make themselves acquainted with our machinery for relieving the sick poor, the more thoroughly will that social duty be performed. It is just one of those departments in which the public may most safely aid the profession, and in which, with men of real benevolence, there is no risk of the medical man's province being invaded by those who do not understand its duties and responsibilites. It is our intention, as soon as time and space permit, to take up this question at length. Meantime, we devote a paragraph to the most recent work on the subject. Dr. Oppert's volume[1] has laid on our table several months, and our excuse for allowing it to do so is, that it is to a certain extent a book of reference, although it may be read through at once by any one in search of information about the various charities included in the title. It is a volume of more than 200 large 8vo pages, and illustrated by 58 woodcuts. It is divided into two parts. The first treats of the construction and administration of charitable institutions. The second comprises a series of descriptions of existing institutions in Great Britain and on the Continent. To the profession, the second part will, no doubt, prove most useful. Here they may find an account of important hospitals in America, Belgium, Denmark, France, Germany, Holland, Italy, Russia, Spain, and Switzerland. The part allotted to Great Britain is of course very liberal, and the London Hospitals take up the largest share of attention. In these also, the *special* as well as the *general* hospitals are also represented — the author finding some of them, such as the Consumption Hospitals and Lock Hospitals amongst our most important charities. The account of the German and French Hospitals is also very full, and the work, as a whole, has an appearance of completeness that will gratify those who refer to it. In a future edition, descriptions of newer institutions as they become developed will, no doubt, be inserted. The amount of labour bestowed on a book of this kind must be immense. The mere collection and compilation of the facts, would occupy months, and when we add that Dr. Oppert has visited, and personally examined a large proportion of the institutions he describes, both in these islands and in France and Germany, the reader will at once comprehend how reliable is the information thus brought together. We know of no other book in the language with which it can be compared. The immense number of details here collected, distinguish it as a mine of facts which should be studied by Committees, Boards of Guardians, and all other persons upon whom may devolve the duty of assisting in the construction, or in the management of institutions devoted to the relief of the sick. As such, we should be glad to see a copy laid on the table of every such charity whenever the governing body assembles for the transaction of business.

1 Hospitals, Infirmaries, and Dispensaries: their Construction, Interior Arrangement and Management, with Descriptions of Existing Institutions. By F. Oppert, M.D., Physician to the City Dispensary. London: Churchills. 1867.

THE PROGRESS OF SURGERY.

Many of our readers will remember that in 1864 and in 1865 Sir William Fergusson delivered some lectures on the recent progress of Anatomy and Surgery at the Royal College of Surgeons. They were reported more or less fully in the medical journals at the time, and appeared in the *Lancet, in extenso*, with illustrations on wood. Sir William has lately republished them[1] in a handsome 8vo volume, and in this form they will, no doubt, obtain a wider circulation in the profession, as they are well worthy of a place on the shelves of all surgeons. We have said they are on the progess of surgery; for although the Chair of Anatomy was also filled by the author, it is undoubtedly as a surgeon that he was most looked to, and to surgery the larger part of the work is devoted. We may go further and add that it is to these advances which are due to the distinguished lecturer's own labours that the fullest consideration is here given—a very natural thing, indeed, for a man whose name is so closely identified with so many of the advances that have taken place of late. The lectures are reprinted in this volume in their original form. The only disadvantage of this is that the lecturer was limited by time in the treatment of his subject, so that there is ample room for additions. In giving, however, the lectures as they were delivered, Sir William has felt precluded from making these, although they would doubtless have been gladly received by his readers. We are pleased to say, however, that he holds out a hope that at some future time he may undertake a more exhaustive work on the subject. We sincerely trust he may be able to carry out this idea, for a complete history of anatomical and surgical progress during the present century could not fail to please and instruct an immense number of professional readers, while it would possess a further interest as the production of one whose surgical genius has engraved his name so deeply upon the record. At the same time, the present volume will retain its value as a reproduction of the two courses of lectures we have mentioned, in the precise form in which they were delivered.

1 Lectures on the Progress of Anatomy and Surgery during the Present Century. By Sir William Fergusson, Bart., &c., &c. London: J. Churchill and Sons. 1867.

MERCANTILE MARINE.—Dr. Arthur Austin Davis, M.R.C.S.Eng., has just been appointed an Inspector of Anti-scorbutics, under the recent Merchant Shipping Act, for the port of Fowey, Cornwall.

MEMORIALS have been presented by the Medical students of Aberdeen to Professor Pirrie, of that University, and to Drs. Keith and Fiddes, Surgeons to the Royal Infirmary, congratulating them on the success of their endeavours to improve and extend the practice of acupressure.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 26, 1868.

REPRESENTATION OF THE UNIVERSITY OF LONDON.

WE last week inserted some remarks on Dr. WOOD's retirement, written by an eminent graduate of the London University, who is fully conversant with every movement that has agitated that important constituency, and who, together with many others, fears lest the Medical Graduates will not secure a representative as alive to their interests as Dr. WOOD was always found to be. We trust these fears may not be realized, and proceed to add a few words respecting the coming contest.

We have all along, as our readers will remember, asserted that the University could find a worthy representative among its own Graduates, and we have urged the great claims which a medical graduate would have in the profession. It was anticipated, at one time, that a medical graduate would be found to contest the seat with a fair prospect of success, and, apart from political partizanship, we regret the present want of such candidates.

If the University graduates intend to go beyond their own ranks for a member, the next most desirable thing is to obtain a gentleman of acknowledged position and attainments in the world of mind. The selection of a merely political notoriety for the sake of the *éclat*, seems to us just one of these things that a learned body ought to be above; while such a pre-eminently scientific reputation as that possessed by the University of London surely ought to give a candidate of scientific renown a claim on the suffrages of the electors. We have, perhaps, gone as far as will be expected in advocating the claims that a Medical Graduate would have, were he to offer himself as representative of his *alma mater*. Yet the medical part of the constituency is of so great weight in this case, that we cannot refuse, in the interests of the profession, to canvass the merits of those who seem ready to serve it.

We have, on a previous occasion, spoken of the great scientific value of Sir JOHN LUBBOCK's investigations, and mentioned some slight indications that the Medical Graduates would find in him a representative ready to defend their rights and urge their claims in all just cases; while the similarity of his pursuits to some of theirs must at all times place him *au rapport* with their wishes. Failing then a medical man, we think Sir JOHN will find great support in the Liberal section of the Medical Graduates. The candidature of Mr. LOWE rests on altogether a different basis. He belongs, indeed, *nominally* to the same political party, but his conduct last session estranged many Liberals, and will, perhaps, render him more popular with the Conservatives. He possesses immense influence in having the open advocacy of the *Times*, though we may doubt whether the leaders of that powerful paper will have on the Graduates of London such an effect as they might on the general public.

As to scientific claims, no one advances them on behalf of Mr. LOWE, and his antagonism to universities is so striking that we wonder it has not provoked more comment. On this point the remarks of the *Spectator*, in an article on the 15th of February, are so opposite that we shall conclude our comments this week by citing them.

The *Spectator* concludes a lengthy and important criticism on "University Elections" as follows:—

"The exclusiveness which insists absolutely and as a *sine quâ non* on a London degree may be exaggerated, but the timidity and self-distrust which abdicate all careful or critical choice in favour of a distinguished name is of far poorer origin. If there is one thing more than another of which any great university ought to be capable, it is of giving young men of remarkable ability or genius, which it has the means of knowing, and which the world at large has not the means of knowing, their fair chance in the political world. And if it postpones such a man who really represents its own highest and most liberal culture, to a mere celebrity whose whole tone of mind is incompatible with its convictions, it is guilty of precisely the same lack of dignity as an ordinary ten-pounder who waives his politics from no corrupt motives, but from sheer inability to resist the overpowering fascination of "a lord" for his pauperised imagination. Mr. Lowe is perhaps the very cleverest, as he is certainly one of the most distinguished members of the present House of Commons. But you might as well return a bull to represent a china-shop as Mr. Lowe to represent any university at all. He represents the contempt for universities much more than any conceivable university feeling. His Oxford experience, and his violent reaction against it, have spoiled him utterly for the purpose of representing the earnestness, the judicial temper, the intellectual sensibility, the historical feeling, the scientific spirit which the London University, no less than all other universities, necessarily fosters. We have spoken of Dr. Stanley, the Dean of Westminster, for want of an equally well-known layman, as a fair type of true university liberalism. Of course the ideal representative of a university should have more of the spirit of modern science, combined with his ethical, artistic, and scholarly liberalism than it has lain in the Dean of Westminster's way to attain. But what can be more opposed to the spirit of such a man as this than Mr. Lowe's undiscriminating, ill-considered, rough-and-ready anarchical sarcasm, aimed now at some monstrous abuse which deserves to fall, now at some vital principle of all true education? A couple of years ago he wanted to erect a practical art like civil engineering into perfect equality with the general studies of a university, and give degrees indifferently for ability to build bridges and for literary culture. Only the other day he was for giving 'the parents of England the privilege and prerogative to direct the education of their children'—*i.e.*, as we understand him, for relieving the public schools of all right to direct the course of education of the pupils submitted to them. He declared against 'grammar' as a fit study for the middle-class schools. The whole tendency of all his brilliant speeches on these subjects has been to panegyrize utilitarian studies directly tending to advancement in life, and discredit relatively those studies which only teach lads to understand *themselves*. No doubt in taking this line he has made many brilliant hits—and also many equally brilliant misses. But we must say we can conceive no active and vigorous mind better calculated than Mr. Lowe's to *mis*represent any university, however liberal, and cover it with obloquy for blunders which it never shared, and for which it would, nevertheless, have all the responsibility. Mr. Lowe admires information of all kinds, but has, as far as we can see, absolutely no belief in cultivation. Timon of Athens would have been as happy a representative of the Athenians, as Mr. Lowe of any true university which aims at developing equally all the faculties of man."

THE METROPOLITAN POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

THE question of the supply of medicines for the sick poor, referred to in our recent notice of the meeting of the Metropolitan Poor-law Medical Officers' Association,[1] is too important to be summarily dismissed with the passing of a resolution, and we are glad to observe that the meeting, after expressing its regret and disappointment, inspired by the adverse opinion of the Poor-law Board, directed an appeal to be made to the Board to take the necessary measures to "give effect to the intentions of the Legislature." We shall await their decision with interest. Meanwhile, we desire to call special attention to the wording of the 69th section of the Metropolitan Poor Act, which provides that "Expenses incurred . . . after the 29th day of September, 1867 *(inter alia)*, for all medicine, and medical and surgical appliances supplied to the poor in receipt of relief by guardians, under this Act, or any of the Poor-law Acts, shall be repaid out of the Common Poor Fund." Two widely different interpretations of this clause have been suggested. The first assumes that, as it is not specified who shall supply the medicine, the party who does supply it, whether the Medical Officer or the Board of Guardians, is entitled to apply to the dispenser of the Common Poor Fund for reimbursement of the "expenses incurred." The second assumes that, as the salary of a Medical Officer who has contracted to supply the medicine, includes payment for the same; the repayment of the salary out of the Common Poor Fund is virtually repayment of the "expenses incurred," and, therefore, if the Guardians provide the medicine, the salary of the Medical Officer should be reduced by the amount hitherto expended by him in the purchase of drugs. In a strict legal sense there may be some weight in this view of the case, but it would be so opposed to the spirit of the Act, as expounded by Mr. HARDY, and accepted by men of all parties in the Legislature, that we do not think it is likely to be insisted on. And, in illustration of the Guardians' idea of the equity of the case, it is only fair to them to state that in the instances where the medicine has been provided by them under the provisions of the Act, no attempt has been made to reduce the salaries of the favoured Medical Officers, a line of proceeding which, as it has not been overruled, must necessarily have been approved by the Poor-law Board. Surely, then, it is but reasonable and just that all the Medical Officers should be placed upon the same footing.

We are glad to learn that the Poor-law Board have promised to "consider" the request of the Association to revise the salaries of Medical Officers upon an uniform and equitable basis. We cannot conceive with what show of reason or justice they can refuse to do this, and thus terminate the glaring anomalies of the present system. No part of the amount of the salaries is taken from the parish rates. Like the medicine, they are paid out of the Common Poor Fund; and, as heretofore, half the amount will be repaid by Government. The meeting was challenged to settle a basis for calculating the right amount of salary, and we are glad to observe that the subject will be taken into immediate consideration.

The other subjects of discussion—viz., the appointment of dispensers to workhouse infirmaries, and the large amount of desk-work done by Medical Officers, are very important, seeing it is alleged that half the time of some of the Medical Officers is consumed in these duties. Truly it would be a "wise economy" to put an end to the system by the appointment of dispensers, and allowing clerical assistance to the Medical Officer as well as the Master.

The best promise for the realisation of the views of this Association consists in their identity with those subsequently promulgated by the Poor-law Inspectors of the district When Inspectors and Medical Officers agree, there can be little doubt of the result. That all things will work round right in the end we never doubted; but "hope deferred maketh the heart sick." We counsel the Medical Officers to persevere patiently, but firmly, in the course marked out by themselves, and we think we may go so far as to say that when the work is done, and Poor-law Reform is achieved, a future generation, in awarding the share of merit due to the workers in this good and truly national cause, will not be unmindful of the claims of this Association.

1 Vide THE MEDICAL PRESS AND CIRCULAR, page 119.

THE BIRMINGHAM GENERAL DISPENSARY.

THANK-YE doctoring has reached at last an extent which appears to us to require the very earnest consideration, both of the public and the profession. On the one hand, the experience of the Medical Officers of charitable institutions in England abundantly proves that the facilities provided by the benevolent for the medical relief of the poor are most grossly abused, and that the functions of such charities are commonly extended to those who are not only perfectly capable of paying for medical advice and medicine but, in many instances, ought rather to be in the position of contributors to the funds of the institution, than recipients of its charity.

It is a fact that the power of recommending, conferred on the benefactors of these institutions, is most injudiciously exercised in favour of well-to-do tradesmen and artizans, and thus not only is a great injustice unwittingly inflicted on the profession, but an unnecessary burthen of charity is thrown upon those who *do* contribute, and funds wasted on such promiscuous objects which are grievously required elsewhere.

To the profession, gratuitous medical labour has assumed enormous and most oppressive proportions, and is the cause not only of the diversion of an enormous income from its members, but of an amount of unnecessary, unremunerative work, which ought to be applied to other purposes. We think it is quite time that the enormous redundancy of hospitals and dispensaries, and the duties into which medical men are driven in connection with them, should receive attention. The public has become imbued with the impression that they have a right to the gratis work of the profession, a principle which is totally untenable, and which we would disclaim in the strongest terms.

The Medical Officers of the Birmingham General Dispensary have recently experienced the operation of this idea, and have most properly protested against it as inadmissible. Fourteen years since the Medical Officers of the Dispensary made application to the Committee that an *honorarium* should be granted to them in consideration of their services, not as an adequate return for their labours, but as a simple recognition of the obligatory principle. At that time the funds of the Dispensary were low and it was impossible to grant the demand, but now its resources have become so large that, in order to dispose of them, it

is necessary to confer the power of additional grants on the subscribers. Under these circumstances the Honorary Staff considered that their claim might properly be considered, but their application to this effect has been refused. In justice to themselves, and the profession, the Honorary Staff have, with one consent, resigned their offices, and we thank them for having, by the one act, maintained their dignity and enunciated a great principle for their brethren. It must be quite evident that the reason which the Committee assigned for their refusal—that, not being in a position to award adequate remuneration, they ought to give none at all—was only a farcical excuse for a most unjust and niggardly policy towards their Medical staff. We earnestly trust that we may not have occasion to record an unseemly and undignified rush for the posts which these gentlemen have, under such circumstances, vacated, and which can be accepted in the face of such a principle by no medical man who respects his position.

Notes on Current Topics.

Dr. Richardson's Lectures.

THE fifth lecture of this course was delivered on Tuesday the 11th, and would have been noticed in our last number, except for want of space. It was on the influence of anæsthetics on the nervous system. He showed that the whole nervous system is not affected by anæsthesia, except when it passes into death. Otherwise, the pulsation of the heart and the respiration would not remain unimpeded. The brain is the organ chiefly affected by these agents, which, through it, hold consciousness in abeyance. An interesting experiment was shown in illustration of this : a pigeon was narcotized with chloroform, then a rapid intermittent current was passed through its body ; the pigeon appeared at once to be restored, for it opened its eyes, rose from the table, and flapped its wings, but on stopping the current, it was seen to be as fully anæsthetised as before. Similar results were exhibited in a pigeon, of which the brain was frozen. The next point propounded by the lecturer, was how these effects on the brain are produced by anæsthetics. Dr. Richardson concluded from experiments, that the vapours act directly upon nerve tissue, either by preventing the development of force, or by arresting conduction—probably the latter. The lecture was as well attended as the previous ones by an influential audience. The concluding lecture of the course is on Tuesday, March 10.

University of Cambridge.

ALL undergraduates of Oxford and Cambridge may be candidates for the Natural Science Scholarship at Trinity College, and not merely those in their first year, as might be inferred from the announcement recently made. The examination will be in Easter week, and candidates must send in their names, as well as the subjects in which they wish to be examined, to the master of the college before the 18th of March. Further information may be obtained from the Rev. E. Blore, Tutor of the College. This is a scholarship particularly deserving the attention of those who intend to follow the medical profession.

St. Andrews University.

WE are happy to announce that the claims of the Medical Graduates of St. Andrews to the franchise, upon which we have lately several times commented, have been admitted, and that Doctors of Medicine are to be entitled to vote for the representative to be granted by the new Scotch Reform Bill.

Sir William Jenner.

THE chief topic of Medical gossip last week was the baronetcy of Dr. Jenner. Of course it will be readily understood that the title is strictly a court favour, but the services of this able and laborious physician to science are hereby indirectly rewarded. He would be the first to admit the merits of others, and if a particularly industrious career should be in a few instances thus commemorated, it may act as an incentive to others. We feel, however, and that strongly, the disgraceful fact that science is less recognised in England than in any other country. Many years ago, Jenner as well as others, his worthy compeers, had their allegiance been due to a Continental Sovereign, would have received an order of merit, in its country as much coveted as a baronetcy in this. Here it is as if the distinction were given because it is convenient for the attendants of Royalty to have a title. While, therefore, we congratulate the new Medical Baronet on the honour he richly deserves, we think he has more reason to be proud of the more lasting distinction his scientific labours have made for him, and we lament that Royal favour should not be more frequently bestowed on such worthy members of our profession.

Professional Libraries and Reading-rooms.

THE barristers of London have been lately setting forth, as a grievance, which only public opinion can redress, that the libraries of their Inns of Court are closed at sunset, so that they cannot spend an hour in the evening in looking over authorities. The doctors are in quite as bad a case. The libraries of the London Colleges of Physicians and Surgeons are of much less use than they might be, from the early hour at which they close. The College of Surgeons' library is a favourite resort with many, as it abounds in valuable books, and a large number of periodicals, English and Foreign, lie upon the table. The College of Physicians is more conveniently situated for many people ; but its central site in Pall-Mall is neutralized by the short hours for reading, and the small number of journals and books. We believe no public library is open during so few hours in the day, as that of this College, while the Saturday half-holiday is religiously observed. How poor the College is in books may be judged by the notice appended to every summons to a meeting of the Fellows, which is in these words :—"The following resolution was passed at a meeting of the College—'That Fellows and Members of the College who have published works on medical science, be requested to present copies of their works, and of subsequent editions of their works, to the library of the College.'"

Professional Fortunes.

THE golden lining to the professional cloud seems sometimes to be of a very substantial character, and it is at least an encouragement to medical men, in lack of public honours, that they may look forward to the more mundane reward of a handsome balance at their bankers. The metaphoric *acme*, known as "the top of the tree," is a wearisome journey, and seldom reached, but each toiler works on in the hope that he may be the successful competitor, and in his probational drudgery looks forward to the ideal day when

a valetudinarian duchess, as a patient, comes to be nothing but a bore.

Such a limit must have been almost reached by the four physicians, whose wills have been just proved at Doctors Commons for the sums placed against each. Alexander J. Sutherland, M.D., F.R.S., under £40,000; J. L. Morgan, M.D., of Haverfordwest, under £35,000; Charles G. B. Daubeny, M.D., F.R.S., of Oxford University, under £25,000, and J. Knox Vace, M.D., under £18,000.

Nearly an average of thirty thousand pounds each is a most respectable display for four *mere* doctors, and we congratulate our brethren that in these days of two-and-six penny *honoraria* such a record is even a possibility.

The Professorship of Hygiene at the Royal College of Surgeons of Ireland.

THE resignation of Dr. Mapother, Professor of Anatomy and Physiology to the College, of the chair of Hygiene, which he held for four years previously to his election to his present position, was presented to the Council of the College at their last meeting, and as soon as the Professorship has been duly declared by the Council to be vacant, it will be, in accordance with the Bye-Laws, advertised for twenty-eight days previously to the election.

The Professorship is one of those enumerated in the Bye-Laws as to be established in connection with the College, but it is a purely honorary position, no emolument attaching to its occupancy. For many years the functions of the chair remained in abeyance, and no lectures were delivered until the appointment of Dr. Mapother who resuscitated the study of the important subject of the Public Health within the College walls. The lectures of Dr. Mapother were numerously attended, and were published at the time in our columns, and subsequently in book form. The regrets expressed by the Council of the College at Dr. Mapother's resignation of the duties which he had so efficiently discharged, will be re-echoed by all students of the subject of which during his professoriate he had so ably treated.

The Yellow Fever at the Mauritius.

THE War-Office is held responsible for a most foolhardy and injudicious transaction, which claims a rigid enquiry on the part of the public. Our readers have been fully informed of the existence at Mauritius of one of the most virulent epidemics of yellow fever which has ever been recorded. The disease had become greatly mitigated, and the 86th Regiment, which had been kept for some months at the Cape, pending the cessation of the epidemic, were forwarded to Port Louis. By the time they arrived, the disease had broken out with increased virulence, and the population was suffering decimation. Under these circumstances the dictates of prudence would have suggested that the troops should not be landed. Nevertheless they were sent ashore in spite of the unanimous warning of the medical officers of the Port and the Regiment, and placed in the barracks, within whose walls the epidemic had raged only a few months before. The adoption of such a course requires some very remarkable exigency to justify it, certainly some better reason than the obstinacy of the officer in command. We have not heard that the presence of a military force was urgently demanded in the Island, certainly not in Port Louis, where the danger of placing troops was specially evident.

The Election of Coroner for West Middlesex.

As we stated in our last the nomination for this appointment, which has been so vigorously contested for several weeks, and we believe at an enormous cost, and has excited much interest in the Profession, took place at Brentford on this day week, and was as stormy and exciting as if the contest were for the county representation. The show of hands was declared to be in favour of Dr. Diplock, and the poll having been demanded by Dr. Hardwicke, was fixed for Friday.

At the close of the poll the following was the result:—

Votes for Dr. Diplock, 1604.
" " Dr. Hardwicke, 1470.
" " Mr. Walter, 51.

It will thus be seen, that the contest between the medical candidates was very close. The majority for Dr. Diplock was 134, whilst the number *polled* by the legal candidate was modest in the extreme. This unquestionably shows the bent of public opinion to be in favour of a medical man for this important office, and we cannot, therefore, but feel gratified at this further triumph for the profession.

Dr. Diplock employed the powerful organisation of the Liberal Registration Association; and to this undoubtedly, in a great measure, may be attributed his success.

The Senate of the Queen's University in Ireland.

BY order of the Senate, a Meeting of the Convocation of the Queen's University in Ireland will be held at Dublin Castle, on the 14th of April next, for the purpose of electing a Senator, to supply the vacancy created by the lamented death of the late Earl of Rosse.

In accordance with an opinion entertained by a large number of Members of Convocation, that the increasing importance of the Collegiate Medical Schools demanded a larger representation of Medical interests in the Senate, a requisition to Dr. William Mac Cormac, M.A., M.D., F.R.C.S.I., asking his permission to allow himself to be put in nomination for the vacant seat, was numerously signed by members of Convocation connected with the three Colleges, and was subsequently adopted at a meeting held in Belfast.

Dr. Mac Cormac's intimate knowledge of the system and arrangements of the Colleges, derived whilst pursuing the courses of Arts and medicine, his collegiate and university distinctions, and his connection with the Belfast School of Medicine, as one of the attending Surgeons of the General Hospital in that town; as well as the deep interest he has invariably taken in the subject of education, point to him as one eminently calculated to become a useful member of the Senate of the University.

Nicotiana.

WE are concerned to learn that active Englishmen and quick-witted Hibernians are smoking themselves into the laziness of Dutchmen, and the stolidity of Germans, and we prophecy only that which physiology and therapeutics teaches us, when we fore-cast a great and lasting deterioration in the national character under the chronic influence of stupifying sedatives. The quantity of tobacco imported into the United Kingdom, we learn by recent returns, has increased to nearly double the amount in twenty years, and at this day, men, and the abnormities of development designated "youths,"

imbibe enough of the herb to represent twenty-two ounces for every man, woman, and child within the kingdom. The little public interest which attaches to the condition of the livers and stomachs of excessive smokers, merges in a very deep concern for the effect of this endless semi-narcotizing on the mental powers of those who have hitherto made England what she has been amongst the nations.

Irishmen or Frenchmen may, perhaps, be none the worse by having their imaginative temperaments toned down to the fit condition for sober plodding business, by a daily constitutional sedative, but Englishmen, whose nervous system is set to the real pitch for substantial work, cannot but lose by a further relaxation. Those engaged in the study of the different phases of real life, so popular at the present day, have an interesting field for investigation opened to them, in the consideration of how far the epidemic of Dundrearyism and *nil admirari* which has recently invaded the young men of England, and of which one of the symptoms is the twaddle talked against early marriages, may have resulted from a permanent obscuration of energy by the abuse of tobacco.

Rattlesnake Poison.

Of transatlantic experimental physiologists and physicians, one of the most well-known in this country is Dr. Weir Mitchell. In 1860 he published through the Smithsonian Institution, an important monograph on the Poison of Rattlesnakes, in which he added very largely to our knowledge of this subject. Since then he has continued his experiments, and, as he has had occasion to alter some of his conclusions as well as to extend them, he has now issued a new essay on the subject, which will be found in the last number (January, 1868) of the *New York Medical Journal*. The essay occupies 34 pages of the journal, and contains, besides details of his experiments, a most interesting account of his mode of managing the reptiles. The following are the conclusions at which this eminent authority has arrived :—

1. One-fourth of a drop of the venom is fatal to pigeons under the age of four months. One-eighth of a drop is frequently a fatal dose. 2. The venom is absolutely harmless when swallowed, because (*a*) it is incapable of passing through the mucous surfaces ; (*b*) it undergoes change during digestion, which allows it to enter the blood as a harmless substance, or to escape from the canal in an equally innocent form. 3. Twenty-four hours after it has been swallowed, the contents of the bowel contain no poison. 4. The rectum of the pigeon does not absorb the venom, and it causes no injury when placed on the conjunctiva of animals. 5. The venom passes through the membranes of the brain, and more swiftly through the peritoneum and pericardium. 6. When the venom passes through the peritoneum it so affects the walls of the capillaries as to allow of their rupture and of the consequent escape of blood. The same phenomena appear on the bare surface of muscles thus poisoned. This, together with the defect of the coagulability of the poisoned blood, accounts for the excessive hæmorrhage about the fang wounds. 7. The blood globules are unaltered in venom poisoning. 8. The rattlesnake is not susceptible of injury by the venom of its own species. 9. The sulphites or hyposulphites of soda or lime have no antidotal power. 10 Carbolic acid sometimes delays the fatal result, and usually lessens local hæmorrhage. 11. These effects are due to no influence of the acid on the venom, but to a direct effect upon the local circulation of the envenomed part. 12. Carbolic acid has no value as a true antidote, and when given internally does not affect the ordinary fatal issue.

Yesterday (Tuesday), the annual festival in connection with University College Hospital, took place in that institution, when his Grace the Duke of Cleveland, K.G., presided. The usual loyal and professional toasts were given, and heartily responded to, and judging by the influential attendance, and the number of subscriptions and donations announced, we anticipate a handsome addition to this most deserving charity.

On Thursday last, a female dwarf died at Walsall from inflammation of the lungs. She was eighteen years of age, and was nearly double the size round the body to her measurement in height.

A private hospital for patients suffering with diseases o the brain and nervous system (except insanity) is about to be opened in New York by Dr. William A. Hammond, whose name is a sufficient guarantee that the institution will be conducted in a proper manner.

In our number for February 12th, in the article on "New Books," the name of the publisher of Dr. Duncan's "Researches in Obstetrics" was misquoted. This important work, of which a review is being prepared, is published by Messrs. A. and C. Black. The mistake is not of great importance, since the name of Dr. J. M. Duncan is so widely known as a writer on obstetrics. Nevertheless, we think it right to make the correction.

A pamphlet by Mr. Cuffe, M.R.C.S., has been published (by Mr. Lewis) on the Woodhall Spa, midway between Boston and Lincoln. Besides the saline spring containing iodine and bromine in considerable quantities, Woodhall provides baths, hotels, and all creature comforts at a moderate price, and has the advantage over foreign spas of being near London. We lately received a bottle of the water from Messrs. Best and Sons, and duly drank a part of it. We can, therefore, assert that its taste bears out the report of Mr. Cuffe's pamphlet, that it contains the salts found in sea-water, as well as some others.

This week some preliminary arrangements will be completed for the meeting of Medical Council. A general wish has been expressed that it should meet again while Parliament is sitting, and that an effort should be made to obtain an amendment of the Medical Act.

"The physiological actions and therapeutical uses of conium, belladonna, and hyoscyamus alone and in combination with opium" will be the subject of the Gulstonian lectures, to be delivered at the London College of Physicians by Dr. Harley, in the first week in March, and Dr. Bence Jones will follow them with the Croonian addresses "On Matter and Force" in the following week. The Lumleian lectures will be delivered immediately after these courses by Dr. Guy, who has taken for his subject "The Factors of the Unsound Mind, with Special Reference to the Plea of Insanity in Criminal Cases."

Last week, an inmate of the Prestwich Lunatic Asylum, whilst in an infuriated mood, broke the jaws and beat out the brains of an unfortunate fellow patient. The jury, in their verdict, stated that death resulted from injuries inflicted by an irresponsible person.

We learn that Dr. Banks, the Professor of Practice of Medicine in the School of Physic in Ireland, has resigned that office. We believe the value of the appointment is about £300 a-year, and already Dr. Freke and Henry Kennedy are mentioned as probable candidates.

Dr. Lawson has been duly appointed Assistant-Physician to St. Mary's Hospital.

It is likely that Dr. Christison will be called to the Principalship of the University of Edinburgh, vacated by the decease of Sir D. Brewster, whose splendid career we epitomised last week.

We are informed upon excellent authority that no vacancy will be declared at St. Thomas's Hospital in consequence of the resignation of Dr. Barker, as the staff is considered quite sufficient.

We are gratified to be able to announce that the alarming illness under which Mr. Ledwich, the learned chief of the Ledwich School of Medicine in Dublin, had suffered, has completely relaxed in its severity, and that he is making a rapid progress towards convalescence.

Hospital Reports.

KING'S COLLEGE HOSPITAL.

Cases under the care of Dr. BEALE, F.R.S.

(From brief Notes by Dr. Tonge.)

Erysipelas of Face.—A. M., æt. 28, compositor. Admitted October 15; discharged November 12; in hospital 28 days. *Recovery.* Intemperate. Previously ill 5 days. Had been drinking previously. Began with shivering, spread from right eye. Delirium, tremor, and spectral illusions. On 8th day, face very red and swelled; vesication and sloughing about eyelids; tongue dry and furred; pulse 120. On15th day an abscess in right side of neck opened. Well on 22nd day, with exception of small abscesses about scalp.

Liquor ammoniæ acetatis, chloric ether, and carbonate of ammonia (10 days.) Then quinine, dilute hydrochloric acid, and quassia. Opiates; castor oil.

Erysipelas of Face.—R. P., æt. 43, housemaid K. C. H. Admitted June 3; discharged June 13. In hospital 10 days. *Recovery.* Previously ill, 2 days. Shivering and loss of appetite. Spread from bridge of nose. On admittance, face red, swelled, and painful; can just open eyes; scalp unaffected; much headache; pulse 126. Convalescent on 10th day.

Carbonate of ammonia and chloric ether. Pil. Colocynth Co.

Erysipelas of Face.—S. G., æt. 22, ladies-maid. Admitted June 2; discharged July 28. In hospital 56 days. *Recovery.* Previously ill 1 month. Shivering, vomiting, and loss of appetite; followed by erysipelas of face, commencing on right cheek. Three relapses during last month; the last 1 week ago. On admittance, face puffy; cheeks red and desquamating; appetite bad; pulse 80; urine albuminous; no dropsy of ankles. On day face free from redness, but still puffy. Followed by chronic enlargement of right parotid. Albumen did not disappear.

Quinine and sesquichloride of iron. Cod-liver oil Pepsine. Collodion and castor oil to face.

Erysipelas of Face.—M. W., æt. 60, housemaid. Admitted November 7; discharged December 7; in hospital 30 days. *Recovery.* Previously ill 3 days. Began with shivering and anorexia. Spread from right ear. On admission, nose, forehead, and cheeks red, swelled, and painful. Some puffiness of scalp. Pulse 120. Tongue furred. Delirious before admission, and on 6th, 7th, and 8th days. Convalescent on 14th day.

Liquor ammoniæ acetatis, chloric ether, and bark (3 days). Same, without liquor am. acet. (20 days). Then quinine and dilute sulphuric acid. Brandy 12 oz. Collodion and castor oil to face.

Diarrhœa.—Ann E., æt. 27, cook. Admitted August 6; discharged August 12; in hospital 6 days. *Recovery.* Vomiting and diarrhœa 5 days. Some blood in motions. Well on 9th day.

Dilute hydrocyanic acid and bicarbonate of soda (4 days), then quinine and dilute sulphuric acid.

Diarrhœa.—J. H., æt. 30, nurse St. J. H. Admitted October 10; discharged October 20; in hospital 10 days. *Recovery.* Previously ill 18 days. Abdominal pain and tenderness. Much purging. Stools bloody. Headache, nausea, and loss of appetite. Well on 24th day.

Pulv. ipecac. co., aromatic spts. of ammonia, liquor ammonia acetatis, and chloric ether.

Secondary Syphilis.—Mary A. K., æt. 20, servant. Admitted January 19; discharged February 13; in hospital 25 days. *Recovery.* Loss of strength 2 months. Slight cough. Breath very fœtid. Large yellow ulcer at left side of posterior wall of pharynx.

Dilute muriatic acid and bark, grey powder and rhubarb, strong nitric acid to ulcer.

Secondary Syphilis.—J. A., æt. 21, servant. Admitted January 25; discharged April 9; in hospital 75 days. *Recovery.* Pains in bones. Worse at night. Coppery spots on face.

Iodide of potassium and bark, quinine and dilute sulphuric acid, bichloride of mercury and bark. Calomel fumigations.

Secondary Syphilis.—Susan B., æt. 28, married. Admitted May 17; discharged July 2; in hospital 46 days. *Relieved.* Sore 5 years ago, with suppurating bubo. Sore throat 5 months. Copper-coloured eruption 1 month. Tonsils much swelled. Voice husky. Ten days later much superficial ulceration at back of pharynx.

Iodide of potassium and bark, glycerine and sesquichloride of iron to throat; aperients.

Secondary Syphilis.—J. M., æt. 29, commissionaire. Admitted May 30; discharged June 7; in hospital 8 days. *Recovery.* Primary sore, without bubo, 6 years ago. Periostitis 3 months. Nodes on vertex of head, left side of forehead, front of left femur, left 8th and 9th ribs, head and front of left tibia. Free from pain on 7th day after admission.

Bicarbonate of potass and iodide of potassium.

Re-admitted on August 18; discharged on August 31; in hospital 13 days. *Relieved.*

Iodide of potassium and decoction of bark.

ST. GEORGE'S HOSPITAL.

DR. STURGES ON THE FORMS OF PNEUMONIA.

The article, No. XV., in the St. George's Hospital Reports on the forms of pneumonia, by Dr. Sturges, is accompanied by a series of carefully compiled, and highly interesting tables on which the observations are based.

It was in framing the statistical table of the Medical Registrar's Report for 1865, that Dr. Sturges was struck by the very slender bonds which held together, under a common name, affections of the most varied kinds.

Especially does this seem true in the instance of pneumonia, for, on reviewing all the cases of this disease described in the Hospital records, the result, as set forth in

the tables, shows very remarkably how pathological conditions, sufficiently similar to warrant the application of a common name to the series, are associated with every variety of clinical phenomena.

Before proceeding to an analysis of the matter contained in the tables, Dr. Sturges gives a brief summary of the views of writers on the subject of pneumonia, and its modifications; he alludes to the various forms of pneumonia recognised by authors, and shews the difficulty there is in making the clinical and pathological classification of these varieties of pneumonia accord well together.

The objects which the author proposes to himself for elucidation in his present paper are—*First*, a consideration of the causes which may produce the various changes which the lungs undergo in so-called pnuemonia, and the relation of these to the phenomena of true inflammation; *Second*, and specially, by reference to the clinical records of the Hospital, to classify a number of reported cases of pneumonia, in all of which death was ascribed wholly or mainly to that disease.

Notice is then taken of the production of congestion and hyperæmia by mechanical means, causing exudation of coagulable lymph into the tissues, and the pathology of lung consolidation as explained by various authorities, Todd, Walshe, Stokes, and Williams, is thoughtfully discussed. The result the author comes to practically is, that the signification of lung consolidation must be sought by means of its attending phenomena, and that "pathological appearances must be interpreted by the light of clinical knowledge."

Nothing can be more true, or more vitally important than this last remark; mere morbid anatomy is of very little use practically, unless it be combined with clinical history as well. The contemplation of a series of morbid products is interesting no doubt, but unless the clinical phenomena of the case during life are faithfully entered into, the chance is, that morbid anatomy will become almost a separate science, with scarcely more bearing on practical medicine than has the science of rocks or fossils.

The truth of the remark that pathological appearances must be interpreted by clinical knowledge is aptly illustrated by Dr. Sturges in case 9 of Table IV. as compared with case 1 of Table V.

In both these cases the pathological appearances after death were strikingly similar, and yet one patient sank gradually as from continued fever; the other died in a few days suffocated by extreme dyspnœa.

In pursuing his laborious work of tabulating, Dr. Sturges soon found that his cases seemed to fall into four classes as regarded their clinical histories. The *first* and largest class comprised those who died of pneumonia in the course of lingering and exhausting diseases of whatever kind. The *second* class would consist of those who had pneumonia come on in the course of fever, or any form of blood-poisoning. In the *third* class are ranged cases of pneumonia from mechanical causes, as for instance, obstructed circulation from valvular disease of the heart, or from vessels obstructed by fibrinous plugging. In these cases consolidation of the lung is often very suddenly brought about by arrest of the circulation and "sudden precipitation, so to say, of the blood" without any inflammatory action.

Many cases of rheumatic pneumonia are of this nature, and are marked clinically by absence of the usual auscultatory sounds of pneumonia.

Lastly, Dr. Sturges speaks of sixteen cases that he ranges as instances of simple pneumonia; these are all he can find in the records of twenty years at St. George's.

In looking over these cases attention is drawn to the constant presence of pleurisy along with the consolidation. Also, it appears that these simple pneumonias do not by any means invariably affect the lower lobes of the lung. In five cases the chief seat of hepatization was at the apex, and in six the whole lung was solidified. Another point brought out by the tables is that they do not contain a single case of hepatization of the *left* lung only with recent pericarditis, while they contain at least ten in which that is the condition with respect to the *right* lung alone.

These observations show how great are the distinctions between the forms of pneumonia, and that as a common term, it ought to be held to mean little more than a certain combination of physical signs, the truth being that its varieties are so distinct as to be like so many different diseases.

Practically, the result of this kind of careful research and observation is most important; its tendency is to make us think less of the name of the disease and more of its true pathology and clinical symptoms, and so to follow a road likely to lead to scientific and sensible methods of cure.

Finally, we would commend Dr. Sturges' pamphlet most strongly to the careful and attentive perusal of all those who would wish to see "pathological appearances interpreted by the light of clinical knowledge."

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

REMOVAL OF EXOSTOSIS FROM SUPRA-ORBITAL REGION.

By Mr. COLLIS.

On Wednesday, Feb. 12, through the courtesy of Mr. Collis, we had an opportunity of witnessing the removal of an ivory exostosis from the supra-orbital region. The patient, a girl of about twenty-four years of age, had a gradually increasing tumour in this situation, dating from her fourteenth year. It appears to have arisen spontaneously. There had been no pain in the tumour, nor was any produced by it, except at periods of occasional discharge of pus from the eyelid, just over the lachrymal gland. There was considerable exophthalmos; a large mass of hard bony material occupied the roof of the orbit, pushing the eye downwards as well as forwards. With all this displacement, vision was perfect. The tumour further projected over the outer angle of the eyebrow in a rounded mass the size of a small hen's egg; a smaller mass occupied the site of the frontal sinuses, and extended upwards on the forehead. As the girl was anxious to have the deformity removed, Mr. Collis, with the consent of his colleagues, undertook the operation. A single incision along the line of the eyebrow laid bare the centre of the tumour. The soft coverings, including the periosteum, were drawn aside upwards and downwards. The frontal nerve was found to be deeply imbedded in a groove or sulcus in the tumour. Mr. Collis reluctantly divided it. With a variety of saws the most prominent portions of the growth were detached. This was a most laborious and fatiguing part of the operation, owing to the excessive density of the bone, which was as hard as walrus tooth ivory. Mr. Collis having removed as much as was practicable with the saws, used the gouge and hammer very freely to carve out the greater part of the mass which lay along the orbital ridge, and which caused the exophthalmos. Numerous small pieces were in this way struck off by repeated blows, until it became a work of much delicacy and some risk. The gouge forceps also was used, but from the great hardness of the material with little effect. The eyebrow having been in these ways carved into a normal shape, the soft parts were brought together by a few pins and harelip sutures. The girl lost but little blood, and was kept under chloroform during the hour which the operation took for its performance.

The eye appeared to return to its proper horizontal plane, though still somewhat in advance of its fellow. Some of this projection was owing to the depth of the tumour in the orbit, and its proximity in this part to the brain, which precluded any interference with the proper roof of the orbit. Some, however, was no doubt due to the swelling, which the necessarily rough handling of the parts produced.

Among the numerous spectators of this difficult and remarkable operation we noticed Mr. Battersby, who just twelve months ago underwent a somewhat similar operation, in the same theatre, at the hands of Mr. Collis. It gives us much pleasure to state from personal observation, that in his case not only was the symmetry of the face restored at the time, but that now after the lapse of twelve months he continues perfectly free from the smallest sign of relapse. It would require somewhat close inspection to discover the cicatrix of the wound.

Mr. Collis stated that although he could not in the case of the girl now operated on, expect freedom from relapse; yet that by removal of so much hard bone from the front of the tumour, it was to be hoped that the balance of resistance to the spread of the disease would be in favour of the roof of the orbit and the brain, and that if the disease did continue to grow, it would be in the forward direction, where, though unsightly, it would be safe. At the same time, from the great density of the material, any new growth would probably be extremely slow in progress.

Subsequent inquiries enable us to state that this patient has recovered from the effects of the operation without a single bad symptom. The wound healed by first intention, with the exception of one corner, from which a moderate amount of healthy pus continues to be discharged. She was kept in bed for eight days as a matter of precaution rather than necessity.

SURGICAL SOCIETY OF IRELAND.

JANUARY 31, 1868.

Mr. COLLES in the Chair.

DR. DAVYS exhibited a recent specimen, being the second finger of the right hand, which had been torn off under the following circumstances :—A robust young man, about 20 years of age, was managing the horses of two carts, and while in the act of tying the rope which connected the head of the second horse to the iron stay on the tail-board of the second cart, his finger got entangled in the loop; the first horse moved on, the second gave a jerk backwards, and in a moment of time the greater part of last phalanx was torn off, taking with it about 13 inches of the tendon.

He felt not the slightest pain. At the time of the injury some hæmorrhage occurred, which a herd immediately stopped by the application of a styptic, which he was in the habit of using to stop bleeding in cattle, simply the ordinary puff-ball. In consequence of the extent of the injury, he thought it advisable to send the man to the Mater Misericordiæ Hospital, where he was under the care of Mr. Tyrrell. So far as external appearance was concerned, no one looking at the arm would imagine that such an amount of injury had been done. Mr. Tyrrell said—"The man complained of no pain ; and the reason they kept him in the hospital was, that the phalanx being torn off a little above the joint, and there being no covering for the bone, it became necessary to disarticulate the stump, so that there might be some soft parts to cover it, and there was not the slightest inflammation in the arm, or any other bad symptom."

OBSERVATIONS UPON CASES OF HERPES ZOSTER.—BY MR. C. J. MOORE.

No.	Initials and Date.	Age.	Previous Health and Present Symptoms.	Part Affected.	Remarks—Residence, if noted, &c.
1	M., a lady's maid, Nov. 24th, 1859.	24?	Lately had dysentery and now tenderness in left inguinal region.	Left side of waist—half round the body.	Sleeps in an underground room, dark, crowded, and ill-ventilated.
2	M'K., a lad, March, 1860.	14	Has much pain at seat of eruption.	Left side of chest and part of epigastrium same side.	Poor and ill-nourished.
3	M., a woman, Nov., 1860.	45	Had pain in May preceding at part now affected. Suffers much pain now also.	Left side of chest and upper part of left epigastrium.	A poor person.
4	Lady's maid, Jan., 1863.	22	Pain—menstruation delayed a week, and only came on with eruption.[1]	Left side of chest.	Of very fair complexion and delicate skin; cannot use fish, nuts, or ale. When taken ill with herpes zoster was with her mistress on a visit at a nobleman's mansion, but slept in a room in the top story, the sanitary conditions of which were not favourable.
5	A girl, May 4, 1865.	11	—	Right side of chest.	
6	Jane D., May 8, 1865.	7	—	Left side of chest and abdomen.	Living in a very unwholesome lodging in Arthur's-lane.
7	A boy, May 23, 1865.	8	—	Left side.	
8	Wm. C., July 29, 1865.	8	Nausea and vomiting before eruption appeared.	Left lumbar and iliac region.	Living in Stephens'-street.
9	An infant, July 29, 1865.	—	—	Left thigh.	
10	A boy, Jan. 9, 1866.	6	—	Left side of chest and abdomen.	
11	H. F., a boy, Jan. 20, 1866.	age not noted.	—	Left side of chest.	Eruption healed, and scaling off upon 27th January.
12	Edward M., Jan. 22, 1866.	12	Pain not complained of.	Over left scapula and in axilla.	Erysipelas prevalent at this time in the same district.
13	Eliza K., March 20, 1866.	40	Subject to (gastric?) pain —unhealthy looking.	On gluteal region, left side.	Experiences severe darting pain in part affected, and down to knee.
14	A child, sex not recorded, Sept. 10, 1866.	12	—	Right side of chest and back.	Living in 8, Church-lane, in a crowded and unhealthy tenement close to St. Kevin's Churchyard.
15	Theresa E., Nov. 7, 1866.	4	—	Right side of chest, abdomen, and back.	Living in 3, Oliver's-alley, a very dirty and unwholesome place, close to stables.
16	Kate B., Nov. 8, 1866.	3	Pain not complained of.	Right side of chest, abdomen, and back.	
17	A young woman, Jan. 12, 1867.	19	Pain not complained of. No irregularity of health.	Left side of chest and back.	

1 See case of recurrent herpes mentioned subsequently.

CASES OF HERPES ZOSTER.—*Continued.*

No.	Initials and Date.	Age.	Previous Health and Present Symptoms.	Part Affected.	Remarks—Residence, if noted, &c.
18	John M., Feb. 16, 1867.	16	—	Left shoulder and arm.	
19	Martin B., July 20, 1867.	7	Just before eruption appeared had severe pain, which caused him to awake crying in night.	Left side, extending from spine round to centre of body.	Living in a cellar in Cuffe-street; unhealthy-looking child—pale, and with red hair. The vesicles are run into one another, being mostly as large as a fourpenny-piece. They are of a purpuric or hæmorrhagic colour.
20	Ann D., 25th Sep., 1867.	19	Menstruation is present; eruption commenced (with pain in heart and itching at part affected) some days before menstruation.	Left side of chest from spine round to front of chest and epigastrium.	Living in top storey of a house in Aungier-street; delicate. Fresh vesicles came out eleven days after eruption first commenced. Menstruation was excessive. Cardiac pain continued during eruption.
21	A woman, E. G., 8th April, 1867.	60	Complains of irritation of eruption.	Across neck and upper part of chest (position upon the latter not mentioned).	
22	Patrick W., 15th April, 1867.	15	Great pain in affected part.	Left side.	Residing in Aungier-street.
23	Catherine C., Aug. 15, 1867.	49	Great pain in the vesicles and in the chest.	Four bluish patches (purpuric) of vesicles on left arm and same side of chest.	Living in ill-ventilated and filthy tenement in Goodman's-lane, a very dirty place.
24	Jas. D., 4th Nov., 1867.	7	A small child for his age: has cough; not much pain from eruption.	On abdomen, hip, and groin, left side. In this case sloughing succeeded the eruption.	Living in a house excluded from light and air by bank of Canal-harbour, Portobello, on a damp ground floor.
25	Jas. S., 30th Nov., 1867.	11	No pain unless eruption be touched, as by clothes.	Left side of chest and upper part of abdomen.	Living in front attic of a house in Bride-street.
26	Matilda R., 17th Dec., 1867.	7	Had fever, and was in Cork-street hospital last April; had pain in bowels some days prior to eruption.	Front and right side of chest, and slightly exceeding mesial line of back; in some parts great pain preceded eruption by some hours, and occurred at night.	Living in attic in Hanover-lane, a confined and crowded locality.

Age.—The average of the 25 cases, whose ages were recorded, was a little over 17 years.

Of the 26 cases of herpes zoster of the neck, trunk, and thigh, one case occurred in an infant, under a year old, one in a girl of three years, and another in one of four years, and one in a boy of six. Four children of seven years of age had the disease; two being boys, and two girls. Two boys of eight years suffered from the affection, as did also a boy and a girl of 11 years. A boy of 12, and a second child of same age, whose sex is not recorded, as well as two lads, aged respectively 14 and 15, presented instances of the disorder, as did also a lad of 16.

Two young women of 19 years, one of 22, and one of 24, as well as four women aged respectively, 40, 45, 49, and 60, afforded some evidence of the more frequent occurrence of the disease in the adult female, than in persons of corresponding age in the other sex.

The exact age of one boy was not noted.

Sex.—In persons at and under 16 years of age, cases far more frequently occurred in males than in females.

I may observe that Mr. Hutchinson of London, who has recently given his experience of the disorder, found, of all ages, 37 males to 26 females. Bateman regarded it as most common between 12 and 25 years of age, the aged he found were not, however, exempt from it, and suffered severely from the accompanying pains.

It has also been observed as more tedious in healing, in advanced life, as might be expected.

In no case have I seen the disease truly encircle the body. Such cases have, however, been recorded; the popular and ancient idea, that such an event would prove fatal, is now exploded.

Season.—Bateman regarded the disease as more frequent in summer and autumn. Of the cases recorded by me, seven occurred in winter, seven in spring, four in summer, and eight in autumn. I should observe that I reckoned winter to include December, January, and February; spring, March, April, and May; summer, June, July, and August; and September, October, and November as autumn.

Side of the body upon which herpes zoster more commonly occurs.—Of my own cases, I find that in twenty it was situated upon the left of the mesial line. In one case, that of a woman (numbered 21) who was 60 years of age—the note I made at the time, states that the eruption extended *across* the neck and upper part of chest, resembling what has been by some authors regarded as an instance of the eruption, as encircling the body. In only five of my cases was the right side affected. I will now quote the following upon the subject:—

	Watson.	Mehlis.	Rayer.	Fenger.	Bärensprung.	Hutchinson.	The Writer. Day.	Total.
On the right side ...	10	16	37	24	24	32	5·3 =	151
On the left side ...	5	9	16	20	32	30	20·2 =	134

Practically we may repeat the statement of Mr. Hutchinson, that "*herpes zoster occurs with equal frequency on the two sides.*"

The state of the blood and urine in herpes zoster, does not seem to afford any constancy according to Rayer, Keller, and Bärensprung.

When the eruption, early in its course, assumes a purpuric appearance, much pain is felt in the part, and as might be expected, a greater proneness to sloughing and tediousness in healing exists.

The premonitory stage of indisposition, the febrile stage, varying in degree, and that of healing and desquamation, have all been so well described by Bateman, that nothing need be added thereto.

The exact nature of the affection appears still, however

shrouded in obscurity, its intimate connection with the state of the nervous system, would appear from the writings of some of the oldest authors upon the subject, many of whom attributed its occurrence to fits of anger, while in recent times, Professor Von Bärensprung, Mr. Wilson, and others, have drawn attention to the intimate relation existing between the seat of the affection, and the distribution of the tegumentary filaments of nerves.

Why the disorder should appear, almost always, only unilaterally, is one of the peculiarities of this affection.

That a certain degree of periodicity attends the pain, which often not only precedes and co-exists with, but frequently remains after, the disappearance of the eruption, rather points to what is generally known as a malarial origin, or as I would prefer to term it, a depraved state of the blood, either endemic or individual, so to speak—and, if I recollect aright, Dr. William Moore has recently expressed somewhat similar views regarding the disease.

That it occurs in persons possessing a sensitive and delicate skin, perhaps, may account for its invariably appearing in but one member of a household, while this very fact would appear to prevent our laying too much stress upon its relation to such external causes as malaria.

In three or four cases I observed an apparent connection between herpes zoster and the periodical changes of females.

Cold temperatures appear to exert a decided influence upon the production of herpes zoster, as evidenced by cases given by Mr. Wilson, Mr. Paget, and others. A case in which a patch of herpes, upon one temple, owing, as the patient thought, to his having slept with that side of his head near to a wet coat, occurred in my practice lately. Von Bärensprung regards sudden changes of weather and youth as propitious to it; he does not think sex influences its production, and he asserts it is not epidemic.

Much difficulty attends the classification of herpes zoster; it does not present the characters of an exanthema, as Mr. Hutchinson says, in its absence of symmetry of constitutional disturbance and of contagion; here, however, I may observe, that, like the eruptive fevers, it is almost never known to occur twice in the same individual. If we regard it as a neurosis, the last-named author well observes, why should it not relapse, and have stages, and how can it protect against a second attack.

Mr. Hutchinson, with much reason, is disposed to regard the disorder as constituting a new group by itself.

Mr. Paget's cases, as mentioned by Dr. Woakes,[1] and the contributions of Hutchinson of London, and of Mitchell Moorhouse, and Keen of America, afford matter of deep interest in connection with the results following injuries to nerve trunks, and the important pathological changes sometimes following herpetic eruptions. It is not my intention in this paper to more than allude to these points; I must content myself by merely observing, that "necrosis of the alveolar border of the jaw" followed neuralgia and herpes of the face, in a case of Mr. Paget's. That iritis, superficial ulceration of the cornea, and much damage to the eye is liable to occur in cases of herpes frontalis, as recorded by Hutchinson.

The American war has afforded some most interesting examples of affections following injuries to nerve-trunks.

Division of the nerve, as in Mr. Hooker's[2] case, may cure cutaneous affections and neuralgia. Other cases of division of the same nerve, the popliteal, followed by recovery in morbid states of the skin and neuralgia, are recorded.

Mr. Hutchinson speaks of "a remarkable form of syphilitic rash, so closely similar in all its features to the true zoster, that it is very possible mistakes may have occurred." This form of disease is always symmetrical, seldom limited to the chest, and does not disappear nearly so quickly as the true shingles.

Treatment.—From my own experience, I am led to recommend warm and mildly astringent applications, if any, in the treatment of herpes. Professor Hebra condemns "the ectrotic mode of treatment, that is to say, the destruction of the individual vesicles by means of nitrate of silver.

He says that any plaster which contains but little turpentine, spread upon long strips of leather or linen, and dusted over with powdered opium, especially if supported by means of a bandage, will, at least, in some cases, relieve the severe pains. He does not put much confidence in the use of internal remedies, though, in some cases, he has known narcotics, with or without quinine, apparently remove the pain.

1 *Journal of Cutaneous Medicine.*
2 *Lancet*, 1859.

I may observe, that an interesting case is recorded by Dr. M. Singer, in which the disease followed all three branches of the fifth nerve, and in which the two senses of touch and taste disappeared, and reappeared in strict unison, thus giving strong corroboration to the idea that the gustatory is a nerve of taste.

Some advocate the local use of chloroform, one or more parts to five of oil, in severe neuralgia with herpes zoster.

Preparations of iron, muriate of ammonia, extract of Belladonna and other remedies, have been recommended internally. Professor Hebra has known the severe pain preceding herpes zoster resemble that of pleurisy, and Mr. Wilson has known pericarditis similated in the same way.

Some have found flying blisters to arrest herpes zoster.

As to internal remedies, my own experience induces me to treat every case on its own merits, endeavouring to correct any error of function, nutrition, &c., as far as possible.

In conclusion, I may add, that herpes zoster appears likely to reward those who will undertake the thorough investigation of the subject, in its practical, physiological, and pathological bearings; affording, as it seems to me, in common with other forms of herpes, a valuable sign of diseased action, whose interpretation we by no means as yet fully understand.

ARMY MEDICAL SCHOOL, NETLEY.

EXAMINATION of Candidates for Assistant-Surgeoncies in H. M. Royal and Indian Armies, held at the close of the 15th Session of the Army Medical School, from 3rd to 8th February, 1868.

A. WRITTEN EXAMINATION (3 hours allowed for each subject).

I. HYGIENE. (Prof. E. A. Parkes, F.R.S.), Monday, 3rd Feb., 1868.

1. Give a general sketch of the construction of barracks in the United Kingdom, as now fixed by regulation, and state how the ventilation is provided for. What quantity of water is allowed per head, and what are the chief points to which you would attend in ascertaining and in maintaining the purity of the supply?

2. What are the meteorological instruments used in the Army Medical Department? What are the thermometrical observations of most importance, and how is the dew point learnt from the readings of the dry and wet bulb.

3. Give a short sketch of the chief conditions at Gibraltar, which might affect the health of the troops.

4. What are the numbers of admissions and the rate of mortality per 1000, in the presidency of Bengal in the early part of this century? What are the rates now? Give briefly an account of the chief causes of the change. Explain *shortly* the causes which affect the ratio of deaths to *admissions* in tropical climates.

II. PATHOLOGY. (Prof. W. Aitken, M.D.) Tuesday, 4th February, 1868.

1. Give the necessary details for determining the *external* measurements of the heart, as you have seen them measured in the post-mortem room. State the average measurements of a normal-sized heart, between the ages of 20 and 40; and give some account of the direct and indirect consecutive diseases or lesions induced by hypertrophy of the heart.

2. Name the general diseases in which pericarditis is apt to occur. Name them as near as you can in the order of its relative frequency of occurrence. Describe the characters of the new material (undation, fluid, and solid) which is enclosed in the sac in the various forms of pericarditis.

3. Description of post-mortem examination, and commentary:—

On the 7th January, 1868, there was an inspection of the body of Patrick John Williams, who died on the 5th January. He had been ill for ten years. He was 35 years old when he died. It is believed he contracted his ailments in the East Indies. He had completed eight years of service—at home from 22nd December, 1859, to 23rd November, 1863, and in the East Indies from that time till 23rd November, 1867, when he arrived at Netley.

He suffered from acute dysentery at Kamptee. On the passage home he became scorbutic.

At home he had previously suffered from primary and secondary syphilis, and his family history told of hereditary phthisis.

He was invalided on account of chronic dysentery, and on admission to Netley, he was in a debilitated and scorbutic state, with symptoms of chronic dysentery. A sycostic bruit was detected at the apex of the heart.

On the 16th December, he complained of difficulty of breathing. On the 20th he became very weak and feverish, and expectorated blood-tinged sputa. Latterly, the pneumonic symptoms declined. On the 1st January, his condition was that of extreme exhaustion, with dullness on percussion over a large area, bronchial breathing, and bronchophony; no cough, nor expectoration. There were bedsores. On the 2nd and 3rd he passed blood *per anum*, the loss of blood being preceded by marked lowering of temperature.

On the 5th January, his respiration became spasmodic, pulse 86, weak and irregular; abdomen tympanitic. Temperature 87° Fahr. Passing blood *per anum* and from nose. Large mucus râles over chest. Became comatose, and died at 10.30 P.M.

Describe the condition.

a. The lungs.

b. The pericardium.

c. The heart; given the measurements of it, and of its orifices.

d. The colon.

e. The liver, spleen and kidneys; and conclude with a pathological summary on the whole case.

III. MILITARY SURGERY. (Prof. T. Longmore, C.B., Dep.-Inspector-General), Wednesday, 5th February, 1868.

1. Enumerate the various articles of equipment which are placed at the disposal of army surgeons, to assist them in the execution of their professional duties, when they accompany troops on active service.

Give a sketch of the system on which the equipment, as a whole, has been arranged, and indicate the special objects of the articles severally.

2. What are the principal sources of danger when the knee-joint has been penetrated by a bullet?

Describe the various modes of treating these wounds which have been had recourse to in recent wars, and the general results of the experience which has been thus gained.

Mention also the results of amputation at the knee-joint, in the French and English armies in the Crimea, and in the northern armies during the war of the rebellion, in the United States of North America.

3. What quality of vision is necessary to enable a soldier to become a good marksman, at all the distances for which the rifle can be adjusted?

How do you diagnose and estimate defects of vision, pathological changes being excluded, which unfit a soldier for becoming a good marksman?

IV. MILITARY MEDICINE (Prof. W. C. Maclean, M.D. Dep.-Insp.-Gen.), Thursday, 6th Feb., 1868.

1. Give a brief summary of the rise and progress of cholera from the year 1817 to the present time.

How does the propagation of the disease appear to be affected

a. By temperature;

b. By rainfall;

c. By excessive dryness;

d. By the wind;

e. By elevation above the sea level;

f. By the agency of water; and,

g. By excessive fatigue, as in the course of long marches?

Give the best account you can of the so-called "Cholera Fungus," more especially with reference to Professor Kallier's experiments and conclusions.

2. What is the most usual premonitory symptom of cholera?

How long should this symptom last to bring it within the proper signification of the term "premonitory?"

Describe the symptoms of a well-marked case of cholera, in the order of their occurrence, distinguishing the stages.

What is Dr. Johnson's theory of the stage of collapse, and by what arguments is that theory supported?

What is the temperature of the surface, and what that in the rectum, in the algide stage?

Describe the intestinal discharges in cholera.

What is the prognostic significance of bloody evacuations?

What are the chief dangers in the stage of reaction?

3. What is the first and most essential measure to be taken when cholera attacks a regiment?

a. In barracks.

b. In the line of march in India?

How are the evacuations of the sick to be dealt with?

Give, to the best of your knowledge, the therapeutic value of

a. Purgatives;

b. Astringents;

c. Opium;

d. Stimulants; and,

e. Saline injections in the treatment of the disease.

B.—PRACTICAL EXAMINATION (Friday and Saturday, 7th and 8th Feb., 1868).

I. MILITARY MEDICINE AND SURGERY (Fifty minutes allowed).

Examine the case of . . .

Write, concisely, a history of the case; your diagnosis, prognosis, the probable effects of treatment, and the influence of the disease (or injury) on the man's fitness for service as a soldier.

II. MILITARY HYGIENE (Three hours allowed).

(Friday) 1. Examination of water.

a. Physical examination.

b. Qualitative; and,

c. Quantitative determination of amount of chlorine, sulphuric acid, and hardness; total, permanent, and removable.

2. Reading of barometer, with corrections.

3. Microscopic examination of specimens of starches.

(Saturday) 1. Examination of water for organic matter.

2. Determination of acidity in a specimen of lime-juice.

3. Microscopic examination of starch.

III. PATHOLOGY (Three hours allowed).

1. Prescribe the five morbid specimens indicated by the letters A, B, C, D, E, and in your description state:—

a. The name and exact limits of the parts embraced in each specimen.

b. The lesions shown by each specimen.

c. The probable effects of the lesions shown by each.

d. The probable causes of the lesions.

2. Examine, microscopically, the portions of texture given for examination. Name the organ of which each is a portion, and describe its morbid condition.

3. Name the objects shown under the microscopes numbered respectively 1, 2, 3, 4, 5, and 6.

Correspondence.

THE BRITISH LYING-IN HOSPITAL AND THE LADIES' MEDICAL COLLEGE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have no wish to involve in law proceedings myself or others, and more especially the conductors of a medical journal, which appears to have been misled by the exparte statements, impudent falsehoods, and dis-ingenious insinuations, which contemporary journals have by some amazing gullability been led into publishing.

But I have a right to protest against the doctrine which underlies the argument in your last number—*i. e.*, that an individual is bound to disprove all the calumnies which malignant people may set afloat, and I assert that it is the duty of a journalist to prove his statements or to retract them. Just now my engagements are so heavy, that it is not possible for me to write so long a communication as would be necessary to rebut the various matters, which your article of February 5th assumes to be true. But I will say:—

1. You go out of your way to speak contemptuously and disparagingly of the "Ladies' Medical College," and the "Female Medical Society," which has commenced and still sustains that college. Now, Lord Shaftesbury is the president of the society, and has spoken most warmly in favour of its objects and operations, in public, on several occasions, and so have many other distinguished men, and among the friends and subscribers of the society there are the names of the Duke and Duchess of Argyle, Archbishop Manning, Mrs. Gladstone, Sir Walter Trevelyan, Bart.; Lord Houghton, Sir Francis Crosally, Bart., M.P.; Mr. Ewart, M.P.; Professor F. W. Newman, and many other distinguished persons. Among the lecturers are Dr. C. J. B. Aldis, M.A., M.D., F.R.C.P., Dr. E. W. Murphy, late of University College, Dr. C. R. Drysdale, and others; and I may add, that neither myself nor any one else have any personal object whatever in the work which we have undertaken to co-operate with. I send by

book-post a roll of pamphlets and prospectuses issued at various times by the society, and fully representing all it has done; and I refer your readers to articles in the *Lancet* of May 26th and June, 1865; the *Medical Times* of August 25th, 1866; the *British Medical Journal* of 1864, Vol. II.; and *Social Science* of September 20th, 1867. And I ask you, as a gentleman, to substantiate your offensive insinuations upon that point, or to retract them.

2. You impute that the Female Medical Society has "by a *coup d'etat* ousted the medical officers from their share in the hospital administration," &c., &c. That imputation rests upon a statement which I can only describe as an impudent falsehood, and I ask you to substantiate it, or retract it. I submit to the consideration of an impartial reviewer upon your staff, the accompanying pamphlet which I have thrown together in great haste, as a confutation of every imputation that Dr. Eastlake has uttered on this matter, and been so greedily swallowed by the *British Medical Journal*, and the *Medical Times and Gazette*. I also submit the statement of *the lady*, Miss Frith, late the matron of the hospital, whom Dr. Eastlake has attempted to ruin; and finally, I submit the notice paper of special general meeting of the Governors of the British Lying-in Hospital, which was held yesterday, and at which *every resolution was passed unanimously;* a hearty vote of thanks being given to the board of management by a very large assembly of governors. I may add that I hold in my hand letters from many distinguished persons promising to attend, *if necessary*, and vote for the alliance of the college and hospital, but which was unnecessary to read.

The two following resolutions were the cardinal ones:—

"1. That the gratuitous services of the students of the Ladies' Medical College be accepted and utilised for the benefit of the patients of the hospital, and that the board of management be requested to arrange for the co-operation of those ladies upon the basis contained in the "DRAFT SUGGESTIONS" submitted by Dr. Edmunds, and that the arrangement be subject to any instructions, modifications, or termination which the governors of the hospital in general meeting assembled may, from time to time, resolve upon.

"2. That in order to promote harmony and success in the working of the hospital, Dr. Eastlake be requested to resign the office of physician, and that, in event of the secretary not receiving Dr. Eastlake's resignation within seven days from this date, the board of management is hereby authorised to remove his name from the hospital staff, and to appoint the requisite number of physicians, *pro tem.*, to assist in the charge of the hospital, and that at the next general meeting in May, it be the business of the governors to proceed to an election for the vacant offices in the medical staff."

The conduct of the *Medical Times* and the *British Medical Journal* in this matter has been so disgraceful, that I need only mention the following facts to ensure their condemnation by all honourable men in the profession, and by all out of the profession, who have the ordinary notions of fair play:—On February 1st, Dr. Eastlake's letter was published at length, containing important personal charges, and imputing direct breach of trust to the hospital board of management. Both journals published at the same time an "adjudication" upon Dr. Eastlake's exparte statements.

2. My reply to that letter.

(*a*). As regards the *British Medical Journal*—a well-known gentlemen of its editorial staff called at my house, and not finding me at home, left a note, asking me to "cut it down to about half." I went over the MS. with an experienced literary and medical friend, and he decided that I could not condense it further without direct mutilation. I therefore returned it, and left the editor to take the reponsibility of inserting or omitting it.

(b). When the replies appeared in the journals I found that both of them had sent on my letters to Dr. Eastlake, in order that he might annex a rejoinder, and this rejoinder they supplemented with further "editorial comments."

(c). Miss Friths reply upon the imputations they had allowed Dr. E. to publish upon her was not inserted at all, but was treacherously placed in the hands of Dr. Eastlake.

3. My second reply to the falsehoods incorporated in Dr. Eastlake's rejoinder they did not publish at all, but the contents of it also had come to the knowledge of Dr. Eastlake; nor do they, either of them, publish Miss Frith's reply.

Now, I submit that honourable journalists when they find that they have made a mistake, and put the saddle upon the wrong horse, do not behave in that way, and as the statements which they have published have been the basis of your comments, I am obliged to ask you to publish this letter with any observations upon the accompanying papers that an impartial review may suggest.—I have the honour to be, sir, your obedient servant, JAMES EDMUNDS, M.D.

4, Fitzroy-square, London, W.
Feb. 15, 1868.

[IN dealing with the controversy as between Dr. Eastlake and the board of the British Lying-in Hospital, we cannot permit the merits or demerits of the Female Medical College to be imported into the discussion. We are by no means disposed to condemn the principle on which the college was founded, and we believe that the suspicion with which the operations of the institution have been regarded by the profession is the result of the unnecessarily offensive tone adopted by its advocates towards a large and highly respected section of its members.

We cannot conceive how the cause of female obstetric education can be served by sneering allusions to "man midwives," unless it be to cater for the petty prejudices of strong-minded women. It is the adoption of this line of argument which has depreciated the Female Medical College in professional estimation, and as long as that institution makes use of such means to achieve popularity with a certain class it cannot expect to enjoy the respect of persons of wide views.

Our statement that "the Female Medical Society by a *coup d'etat* ousted the medical officers from their share in the hospital administration," which Dr. Edmunds designates "an impudent falsehood," is not only specifically stated, but vehemently reiterated by Dr. Eastlake, and as it is a simple contest of veracity, and not at all essential to the main question, we desire to suspend our judgment, in the hope that the reasons which induced the original board to omit, as Dr. Edmund's states, the medical officers from their house list, may come to light, and that the profession may be in a position to say how far the Female Medical College is responsible for that act.

The *gravamen* of Dr. Eastlake's complaint—that the board being desirous of getting rid of him, supported their midwife in having secretly, and in infringement of authority and discipline, applied instruments—has not even been denied, and we need offer no apology for warning the profession to abstain from placing themselves in a position of practical subordination to unqualified female practitioners.—ED. M. P. & C.]

THE END OF AN IMPOSTOR; OR, THE EVENTFUL HISTORY OF AN UNQUALIFIED MEDICAL ASSISTANT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—On the 29th of January the body of a person unknown, respectably dressed, was found in the river Roding, near Stapleford Abbots, in Essex. It was in an advanced state of decomposition, but at the inquest was identified as that of a man who had slept at the "Blue Boar" at Abridge, on the night of the 16th January. The deceased had previously called upon one of the medical practitioners in the vicinity, and represented himself to be Dr. Scholfield, of Pickering, in Yorkshire.

A person answering the same description, in April, 1867, called upon the medical men in Reading, and told precisely the same story, and indirectly sought pecuniary assistance. I had made inquiries at that time and since, and have no reason to doubt that the person whose body was found in the Roding was the same begging impostor who has been living upon alms derived from the medical profession for several years. His real name was William Rowland Roscoe. After leaving Bolton-le-Moors, in which place he was apprenticed, he became assistant to the late Mr. Cole, of Pickering, with whom he lived about two and a half years, during which time he became addicted to drinking and public-house gambling. He left Mr. Cole, in consequence of a dispute, in 1851, and then commenced a disreputable career assuming at different times the names of "Rowland" and "Kendall," and latterly that of "Dr. Scholfield," a highly respectable gentleman, still at Pickering, who succeeded to Mr. Cole's practice. He appears to have gone out to the Crimea, and to have returned to his mendicant habits after the proclamation of peace.

I have been thus particular in describing Roscoe's career, because he has largely victimized the profession.—I am, sir, yours obediently,

J. BAXTER LANGLEY, M.R.C.S.

50, Lincoln's-inn-fields, W.C.

DR. LETHEBY'S LECTURE ON FOOD.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—If Dr. Letheby were ten times as great an authority on physiology as he is, he would still be amenable to the bar of reason and logic, and inconsistent statements, even though issuing from him, would not be the less inconsistent on that account. Everything which is not food, except air and water, is a foreign body or poison to the animal economy, and therefore injurious to it.

Every substance forming food for an animal must be assimilable by that animal, and capable of entering into the composition of its blood.

Now, Dr. Letheby informs us that *no animal* has the power of *assimulating* mineral elements, when in an inorganic form; consequently, salt, iron, and all other mineral substances in an inorganic state are not food, but foreign bodies or poisons to the system, and not only useless, but theoretically and practically injurious to it. That this is not the case, I defy you, sir, to prove, and as reason maintains the affirmative, the *onus* of proving the negative, if you can, rests with you. The folly of giving iron in cases of anæmia, and lime in cases of rickets, I have seen over and over again proved, by recovery taking place in many instances where neither iron or lime were administered, whilst in others I have seen the patient dosed *ad nauseam* with both of them, without the slightest improvement in the symptoms for which they were so erroneously prescribed.

It is most natural that you, sir, should believe in the necessity of administering minerals in such and other cases, as I presume you have never seen them treated without them, but the experience of those who have is *very different*, knowing as they do that they not only recover without them, but much better than with them.—Your obedient servant,

RICHARD GRIFFITH, Ch.M.

DR. SINCLAIR AND MR. PHELAN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Though you state in your last issue, at the end of Dr. Sinclair's letter, that "We must here bring the correspondence to a close," I trust you will publish my reply to the several *new* matters which Dr. Sinclair has introduced in that long letter. I have made no attack on Dr. Sinclair, either in the paper in question or otherwise. I am merely defending myself, and I expect to be permitted to reply to that letter through the medium in which it was published. Should you allow me to do so, I shall send you the reply shortly. If you do not, I request you will publish this note in your next issue, that your readers may learn why Dr. Sinclair is not answered in THE MEDICAL PRESS AND CIRCULAR.

February 15, 1868. DENIS PHELAN.

Medical News.

THE MEDICAL SOCIETY OF LONDON.—On Monday, the 2nd March, the general meeting of the Society takes place, for the election of officers and council; after which, Mr. Adams reads a paper on "the treatment of wounds upon antiseptic and subcutaneous principles."

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At the quarterly examinations held on the 18th and 19th instants, the following gentlemen passed the second half of their examination for the letters testimonial, and were admitted licentiates of the College, viz.:—George Boyd, Edward Hadden, Edward T. Lloyd, John P. Long, George J. Mackesy, Robert St. John Mayne, Terence J. M'Grath, Andrew M'Munn, William Morrison, Gregory Sale, Robert Spence, Albert J. Watson, and Richard J. Wheeler.

NOTICES TO CORRESONDENTS.

J. COOKE, Esq., Manchester (new subscriber), is thanked. The alteration in address has been attended to.

Dr. SUTHERLAND.—Thanks for enclosure. The journal shall be sent you regularly to Bellingham as requested.

The gentleman who remitted a *Post Office Order* from Worcester, will oblige by forwarding his name and address, that a receipt may be sent in due course.

F. E. S.—We are indebted to you for the interest you have displayed. The back numbers from January 1, 1867, have been dispatched to the address given.

We have to acknowledge the receipt of some specimens of cocoa from Messrs. Cadbury, Birmingham.

THE LATE ELECTION OF CORONER FOR MIDDLESEX.

LEGAL PROCEEDINGS.

WE learn, as we are going to press, that proceedings will probably be instituted by Dr. Hardwicke without delay to quash the election of Dr. Diplock, recorded in another part of our issue, on the allegation that a very large proportion of the votes received on behalf of Dr. Diplock were those of persons not qualified under the Act of Parliament, and therefore illegal.

The majority for Dr. Diplock was only 134; so that if Dr. Hardwicke be enabled to substantiate the statements of his friends, a very much larger number of votes than the majority of the successful candidate will be invalidated.

A CORRESPONDENT forwards to us a communication, which had been received from a Dr. J. Kennedy, of 15 Richmond-street, Portobello, Dublin, which requires an explanation, and one which we trust will be satisfactory and immediate from that gentleman.

It appears that the following advertisement has lately appeared in the Dublin *General Advertiser*:—

"MEDICAL ASSISTANTS, Qualified and Unqualified, having satisfactory references can be suited with situations in England on moderate terms. Only a few days notice required, when most eligible vacancies can be obtained by application to."

To this notice a provincial surgeon replied, asking for information, when, after a week's delay, he received the following note:—

"15, Richmond-street, Portobello,
"Dublin, January 27th, 1868.

"DEAR SIR,—In reply to yours of 23rd inst., I have several in-door and out-of-door vacancies for medical assistants, qualified and unqualified, in England. My terms for each successful engagement are £2 2s., paid in advance. By hearing from you, enclosing me a remittance amounting to the above fee, I shall at once put in force your request, and let you know all particulars by return, &c.—Faithfully yours, "JAMES KENNEDY."

Very reasonably considering it an unusual course for a medical agent to advertise under assumed initials, and to require payment of a fee of £2 2s. in advance, the gentleman wrote to a friend in town as to the reliability of Dr. Kennedy, and the negotiation, of course, went no further.

We should be glad to be informed by what means Dr. J. Kennedy expected to be able to obtain the English assistantships which he advertised that he could provide, and for which he required payment in advance; and we venture to say, that unless he possesses some facilities for negotiating such appointments, the fact of his publishing, and communicating by letter the statements which he has made, requires the most serious attention of the licensing body to which he belongs. The letter addressed by him to his provincial correspondent is written on the fly-leaf of a trade circular, from which we take the following extracts:

"SURGERY, 15, Richmond-street, Portobello (opposite Lennox-street) Dublin. Dr. J. Kennedy respectfully intimates to his patients and the public generally, that he continues to practice at the above address, where he may be consulted professionally. He would pay the most diligent and prompt attention to communications by letter, where his attendance or advice and medicine would be required.

"Dr. Kennedy having had considerable experience in Dental Surgery, would be most happy to afford his services to any patients suffering from affections of the teeth or gums.

"Dr. J. Kennedy attends on all cases of midwifery on moderate terms. He vaccinates children with the most pure and genuine infection, which he obtains specially from the Home Department, Whitehall, London.

"A legal certificate of each successful case of vaccination is given to the parents or friends of children.

"A private surgery is attached, where medicines are specially and carefully compounded for patients, under the direct superintendence of Dr. Kennedy; nothing used but the purest and most genuine ingredients and chemicals.

"As the best guarantee for his qualifications and capabilities, Dr. Kennedy appends testimonials in his favour from several of the most eminent physicians and surgeons."

To this precious document are appended testimonials from hospital physicians and surgeons of the very highest eminence in Dublin. We are well aware that these gentlemen would repudiate the use of their names in connection with so disreputable a transaction, and we therefore refrain from specifying the names, feeling convinced that they will take immediate steps to disassociate themselves from Dr. J. Kennedy and his proceedings.

Communications with enclosures received from Rev. W. Shearley, Wells; T. Corbett, Esq., Kingstown; Dr. Letheby, London; Dr. Horace Dobell, London; Dr. Beale, London; F. Todd, Esq., Horncastle; J. Dr. LETHEBY'S SECOND LECTURE ON FOOD.

COMPARATIVE DIGESTIBILITY OF FOODS—FUNCTIONS OF DIFFERENT FOODS.

(Continued from page 176.)

IT may be said, and truly, that these experiments of Fick and Wislicenus were of too short a duration to afford an opportunity of ascertaining whether the oxydized muscle was not afterwards excreted; but the recent researches of Dr. Parkes on the elimination of nitrogen by two healthy men (soldiers) in the prime of life, during a period of seventeen days, and under different conditions of diet and exercise, have shown that, although the results are not altogether accordant with those of Fick and Wislicenus—yet the conclusions are certainly born out, that a non-nitrogenous diet will sustain the body during exercise for a short time, and that exercise produces no notable increase in the nitrogen of the urine. On the contrary, the amount of urea is actually less during work than at a period of rest; and he thinks that the muscle, instead of oxydizing, and, therefore, losing its substance during labour, actually appropriates nitrogen and grows—its exhaustion being dependent, not so much on its decay, as on the accumulation of the oxydized products of hydrocarbon, as lactic acid, &c., in its tissue, which require rest and time for their removal. That some decay of the muscle takes place, there can be no doubt; for, as Dr. Parkes observes, "although it is certain that very severe exercise can be performed on non-nitrogenous diet for a short time, yet it does not follow that nitrogen is unnecessary. The largest experience shows, not only that nitrogen must be supplied, if work is to be done, but that the amount must augment with the work. For a short period the well-fed body possesses sufficient nitrogen to permit muscular exertion to go on for some time without a fresh supply; but the destruction of nitrogenous tissues in these two men is shown by the way in which, when nitrogen was again supplied, a large amount was retained in the body to compensate for previous deprivation." It would seem, too, from the great exhaustion of the men on the second day of a non-nitrogenous diet, that their muscles and nerves were becoming structurally impaired, and that if the experiments had been continued for a third day there would have been a large diminution in the amount of work. The work which they actually performed on a non-nitrogenous diet of starch and butter, in the form of biscuits and arrowroot, was walking exercise of 23·76 miles the first day, and 32·78 the second. The first day's work occupied, with intervals of rest, about ten hours and three-quarters, and it was done without fatigue; but the second day's work took twelve hours, and the last thirteen miles were accomplished with great fatigue. Calculated according to Haughton's formula, (that walking upon a level surface is equal to lifting 1-20th of the weight of the body through the distance walked), the labour in the two days was for—

	S. Weighing with clothes 162·4 lbs.	T. Weighing with clothes 124·2 lbs.
The first day ...	1,018,676 ft.-lbs.	779,062 ft.-lbs.
The second day ...	1,405,397 „	1,074,817 „
Total work ...	2,424,073 „	1,853,879 „
Total nitrogen excreted...	529·16 grains.	492·46 grains.
Equal to muscle oxydized	3386·92 „	3151·74 „
The energy of which (minus urea) is ...	3,267,361 ft.-lbs.	3,040,483 ft.-lbs.

The amount of nitrogen excreted during the time of actual exercise was only about half the above; and, calculated in this way, it would only account for about two-thirds of the labour-force. The results, therefore, prove that although the basis for the calculations of Fick and Wislicenus was too narrow for accurate deductions, yet the mechanical force of the oxydized muscle is not sufficient to account for external and internal work; and the conclusion is that in the above experiments the motive power of the muscles was not derived from their own oxydation, but from the oxydation of non-nitrogenous matters. The researches of Dr. Edward Smith throw additional light on the subject, for he ascertained that the amount of carbonic acid exhaled by the lungs was in proportion to the actual work performed.

During sleep it was at the rate of ...	293 grs. per hour.
When lying down and approaching sleep...	355 „ „
In a sitting posture	498 „ „
When walking two miles an hour ...	1088 „ „
When walking three miles an hour ...	1552 „ „
And when working at the treadmill ...	2926 „ „

It is highly probable, therefore, that the largest amount of muscular force is derived from the hydro-carbons of our food; not that the nitrogenous matters of it may not also be a source of power; but there is no necessity, as Liebig supposes, for their being previously constructed into tissue. The experiments of Mr. Savory show that rats can live and be in health for weeks on a purely nitrogenous diet, and it is nearly certain that under these circumstances the nitrogenous matters are mostly oxydized without entering into the composition of tissue. This, as I have said, is the main point of divergence from the hypothesis of Liebig; and it is further indicated by the fact that the amount of nitrogen excreted is not in proportion to the work done, but to the quantity of it in the food, even when there is no muscular exertion.

That the chief functions of nitrogenous matters is to repair tissue, there can be no doubt, for animals kept on a purely carbonaceous diet quickly lose weight, and at last die from a disintegration of tissue; but it is equally certain that the nitrogenous constituents of food have other offices to perform. A daily diet of 2lbs. of bread contains enough nitrogen to supply the mechanical wants of the system, but it will not maintain life. There is required an addition of animal food to render it sufficient for this purpose; and indeed the instincts and habits of the human race show, beyond all question, that a comparatively rich nitrogenous diet is necessary for the proper sustenance of life; and it is very probable that it assists the assimulation of the hydrocarbons. In this way it may help in the development of force without itself contributing directly to it; and this may serve to explain the fact, that there is a relation between the amount of nitrogen contained in the food and the labour value of it. Carnivorous animals are not only stronger and more capable of prolonged exertion than herbivororous, but they are also fiercer in their disposition, as if force were superabundant. The bears of India and America, says Playfair, which feed on acorns, are mild and tractable, while those of the polar regions, which consume flesh, are savage and untamable; and taking instances of people—the Peruvians whom Pizarro found in the country at its conquest, were mild and inoffensive in their habits, and they subsisted chiefly on vegetable food; whilst there brethren in Mexico when found by Cortes, were a warlike and fierce race, and they fed for the most part on animal diet. The miners of Chili, who work like horses, also feed like them, for Darwin tells us that their common food consists of bread, beans, and roasted grain.

The Hindoo navvies who were employed in making the tunnel of the Bhore Ghat Railway, and who had very laborious work to perform, found it impossible to sustain their health on a vegetable diet, and being left at liberty by their caste to eat as they pleased, they took the common food of the English navigators, and were then able to work as vigorously. Abundant examples of this description—some of which will be further discussed as we proceed, may be cited in proof of the direct relation of plastic food to mechanical work; but there is no proof that this material must first form tissue before its dynamical power can be elicited.

It is, however, a remarkable fact that all forms of nitrogenous food have not the same nutritive value; the glutinous matters of barley and wheat, though almost indentical in chemical composition, have very different sustaining powers. It is the same with muscular flesh and artificially prepared fibrin and gelatine. Magendie found that dogs fed solely, for 120 days, on the raw meat from sheep's heads, preserved their health and vigour during the whole of the time; but more than three times the amount of isolated fibrin, with the addition of much gelatine and albumen, were insufficient to preserve life.

We may conclude, therefore, that while the main functions of nitrogenous matters are to construct and repair tissue, yet they have manifestly other duties to perform, of an assimilative, a respiratory, and force-producing quality which are far from being understood. What do we know, indeed, of the actual *modus operandi* of the nitrogenous ferments—ptyalin, pepsin, pancreatin, &c., which are secreted so abundantly into the alimentary canal; or of the conjugate nitrogenous compounds which are present in the bile? and how far have we advanced in interpreting the functions of the nitrogenous constituents of tea, coffee, maté, guarana, cocoa, &c., which the instincts of mankind in every part of the globe have evidently chosen for some physiological purpose? The same may be said of the crystalline nitrogenous matters of soup——as creatin, creatinin, inosic acid, &c., which can hardly be regarded as foods, although they have powerful sustaining properties. But enough of this for the present; and before leaving this part of the subject, I would direct attention to the fact, that nitrogenous matters when oxydised in the animal body never yield up the whole of their potential energy, for by being converted into urea, which is the chief product of their decay, there is at least a seventh part of their power lost in the secretion. It may be that this is a necessity arising out of the circumstance, that if they were completely oxydised in the animal body and converted into carbonic acid, water and nitrogen, the last named gas would be unable to quit the system, because of its insolubility in the animal fluids.

Functions of Fat.—The hydrocarbons, which go by the name of fat, differ from other hydrocarbons, as sugar and starch, in the circumstance that the oxygen is never in sufficient quantity to satisfy the affinity of the hydrogen; and, therefore, it is more energetic as a respiratory or heat-producing agent. Its power, indeed, in this respect, is just twice and a-half as great as that of starch or sugar; for 10 grains of it will, by combining with oxygen, develop sufficient heat to raise 23·2lbs. of water, one degree of Fahrenheit, and according to the deductions of both Joule and Meyer, this is equivalent to the power of raising 17,923lbs. one foot high. In cold countries where animal warmth is required, food rich in fat is always preferred; and the fat bacon of the English labourer contributes in no small degree to the production of mechanical force.

But besides this, fat serves important functions in the processes of digestion, assimilation, and nutrition. According to Lehmann, it is one of the most active agents in the metamorphosis of animal matter; and this is seen not merely in the solution of nitrogenous articles of food during digestion, but also in the conversion of nutrient plastic substances into cells and masses of fibre. Elsässer long since observed that during the process of artificial digestion, the solution of nitrogenous foods was considerably accelerated by means of fat; and Lehmann has since determined by actual experiment on dogs, that albuminous substances deprived of fat remain longer in the stomach, and require more time for their metamorphosis than the same substances impregnated with fat. It is probable, indeed, that the digestive power of the pancreatic fluid is due in great measure to the presence of fat; and that the subsequent chymification of food, and its absorption into the blood, is greatly assisted by it. There is also good reason for believing that it is largely concerned in the formation of bile, and that the biliary acids are conjugated fatty compounds. This may account for the well-known action of fat bacon, and other such foods in the secretion of bile.

The digestive power of fat is certainly considerable; and it is no less active in the subsequent conversion of nitrogenous matters into cells and tissues, and perhaps also in their retrograde decay. Colourless blood corpuscles receive perhaps the first impulse of their formation from the metamorphosis of fat; and thus it is an important aid in the genesis of blood. It would appear, too, from the latest investigations of physiologists that it plays an equally important part in every kind of cell development. Acherson showed, as far back as 1840, that albumen always coagulates from its solution around a fat globule, and this is seen in the little fatty particles of milk which have a covering like a cell-wall of consolidated casein. Hunefield, Nasse, and others, have further shown that the nucleoli of cells invariably consist of fat, and that recently formed

plasma always contains more fat than the mature cell. The conclusion, therefore, is that it takes an active part in all the processes by which the nutrient constituents of food are converted into the solid substrata of organs, and so energetic are its powers in this respect, that when the nitrogenous matters of the fluids are not in sufficient quantity to form cells with the fat, it borrows the material from muscular or other tissues, and thus produces a fatty degeneration of the part. This is observed in the muscular structures of over-fed animals, in the tissues of drunkards, who take a large amount of fat-forming food, and in the livers of geese that are crammed with a farinaceous diet.

And not only is it concerned in the formation of new tissue, but it also pervades, and finally disintegrates the older structures, especially when the vitality of them is low. In this manner it helps in the solution and subsequent removal from the animal body of decayed and morbid products of the protein type.

Again, its presence in large quantity in the tubules of nerves, and in the ganglionic centres, would indicate that it performs some highly important functions in nervous action.

And lastly, the distribution of it in the tissues, and the accumulation of it around certain organs, serve to fill up the vacuities of the body, to give rotundity to the form, to equalize external pressure, to diminish the friction of parts, to give suppleness to the tissues, and by its bad conducting quality to retain the animal warmth. Fat, therefore, must always enter largely into the composition of our food, for other hydrocarbons though capable of transformation into fat cannot entirely take its place.

3rd. *Starches and saccharine substances.*—These are well called hydrates of carbon, for the oxygen and hydrogen contained in them are nearly always in the proportion to form water. The carbon, therefore, is alone capable of oxydation, and according to Liebig their functions are entirely calorific or respiratory; but, like other heat-producing agents, they must also have mechanical power, for everything that will raise the temperature of a pound of water one degree of Fahrenheit will by another modification of its action raise 772 lbs. a foot high. These, indeed, are the thermotic and mechanical equivalents of Meyer and Joule. The energies, however, of this class of substances are not nearly so great as with fats, for in the last case, as I have said, there is much available hydrogen, as well as carbon, for oxydation. The diagram which is before you will make this clear.

CALORIFIC AND MOTIVE POWERS OF 10 GRAINS OF THE SUBSTANCE IN ITS NATURAL STATE.

	Lbs. of water raised 1° Faht.	Lbs. lifted one foot high.
Grape sugar	8·4 ...	6477
Lump sugar	8·6 ...	6617
Arrowroot	10·0 ...	7731
Butter	18·6 ...	14358
Beef-fat	20·9 ...	16131

So that, in round numbers, the calorific power of fat is about twice as great as that of starch and sugar, and when dry it is twice and a-half as great.

But these substances have other duties to perform besides the development of animal heat, which is, in fact, the final product of their oxydation, for on becoming changed into glucose by digestion they take the form of various acid compounds, as lactic acid, which occurs in the stomach and in the juice of flesh; butyric, formic, and acetic acids, which are found in the perspiration. The exact functions of these acids are not known to us, although, as I have already explained, the presence of lactic acid in the stomach is essential to the digestion of nitrogenous matters; and perhaps also its occurrence in the juice of flesh is for a similar object—namely, the solution of effete tissues.

Starches and sugars are also concerned in the production of fat. This was once the subject of an animated discussion by Liebig and Dumas, whose views of it were in complete antagonism; but the experiments of Boussingault, Persoz, Lawes, and others, on the feeding of animals, have proved beyond all question that fat may be derived from the hydrates of carbon, and that therefore the views of Liebig were correct. Common experience, indeed, has fully taught us that foods which are rich in farinaceous matters and sugar, are very capable of producing fat.

4th. The *saline* or *mineral* constituents of food are largely concerned in the metamorphosis of matter; and, perhaps, this is their sole function. It is a specialty of these substances to give a soluble form to the plastic constituents of food, and of the animal tissues. They are, therefore, concerned in the phenomena of digestion, absorption, sanguification, assimilation, disintegration, and secretion. In truth they are the chief, if not the only, media for the transference of organic matter from place to place in the animal body—being on one hand the purveyors of nutrient materials into the system, and on the other the carriers of effete substances out of it: besides which, it is very probable that they are the agents whereby liquid colloidal forms of nutriment are changed into solid or pectous, as in the formation of solid tissues from the blood. In the case of digestion and absorption the plastic elements of our food, as albumen, fibrin, gelatin, &c., are not of themselves capable of dialysis, or of passing through the walls of the alimentary canal; and, therefore, absorption must be assisted by some physical agent. This agent is the highly diffusive acids and salts, which are secreted so freely into the stomach during digestion; and it is very probable that they not only effect a solution of the proteinaceous matter of food, but by converting it into peptones, as Lehmann expresses it, they also change the molecular form of the material, and make it pass from an unabsorbable colloid, into a highly diffusive crystalloid. If, indeed, it be, as Mr. Graham supposes, that a colloid molecule is but a group of smaller crystalloids, the action of the saline and acid constituents of the gastric juice might be to break up the larger colloid molecule, and thus give it the property of diffusion and absorption. An opposite condition of things would occur in the alkaline blood, whereby the colloid molecule would regain its structure, and lose its diffusive tendency; but coming to the tissues, where an acid condition of the fluids again exists, it once more changes its molecular structure, and quits the blood to serve the purposes of nutrition. The exact nature of the phenomena that occur when the liquid nutrient matter which thus escapes is changed into solid tissue is unknown to us; but there is good reason for believing that it is no more than a molecular movement effected by the agency of saline matter. In the case of certain structures which contain more than a common amount of mineral salts, this is unquestionably so; for it occurs in the consolidation of the spiculæ of sponges, the calcareous tissues of polypes, the hard dermal structures of the radiata, mollusca, crustacea, &c., and in the calcareous deposits of bone, teeth, tegumentary scales, egg-shells, &c., of the vertebrata. In all these instances the secreted matter must first have been crystalloidal, or it could not have been secreted; it then takes the form of a liquid colloid or jelly; and finally, by a further molecular movement, it passes into the condition of a pectous solid—the saline constituents, according to their nature and proportion, determining the degrees of hardness.

Again, the removal of effete matters, and worn-out tissues, is undoubtedly effected by the agency of saline substances; for, during the processes of oxydation, acid compounds are produced, which by acting chemically on the saline constituents of the animal fluids, give them a solutive power on plastic matters, and thus enable them to remove the debris of worn-out tissue.

(To be continued.)

THE number of soldiers or Royal Marines serving in Great Britain and Ireland who have been flogged since the 12th of April last is as follows:—In the Army (to the 31st of December, 1867), 17; in the Royal Marines (to the 12th of December, 1867), 2.

Original Communications.

DESCRIPTION OF A TUNNEL-HANDLED DOUBLE-BLADED STRICTURE DILATOR, AND TUNNEL-HANDLED SINGLE-BLADED DILATOR AND URETHROTOME CONDUCTOR.

By B. WILLS RICHARDSON, F.R.C.S.I.,

EXAMINER IN THE ROYAL COLLEGE OF SURGEONS, AND SURGEON TO THE ADELAIDE HOSPITAL, DUBLIN.

I PUBLISHED in this journal, on the 20th of last November, the description of a "Stricture Dilator, constructed upon the Dovetail Principle."

In that instrument the handle is formed like the Perrève handle, which is well adapted for preventing wriggling of the conducting-rod, during the process of forced expansion, provided the grasping of the half-handles is sufficiently firm to maintain the forcer in their grooves, as it glides along them.

It is almost superfluous to observe, that tolerably firm pressure applied to the half-handles of the English modification of the Perrève dilator, at present in use, is as necessary, when the forcer is passing between them, as it is with the original Perrève instrument.

Now, the dilator which I described in November last, is so free from risk, during the divarication of the blades, in consequence of the forcer being very accurately retained in a central position, by its dovetailing with the lower blade, that the application of firm pressure to the handle end of the upper blade is not necessary. Indeed, the dovetail dilator may be safely and securely worked, without any handle pressure whatever to the upper blade. Nevertheless, it appeared to me that a handle, capable of allowing the application of slight pressure to the upper blade, for the purpose of facilitating the placing of the dilator in its case, and also for retaining the blades together during the introduction of the instrument, might be advantageous. I, therefore, designed a tunnelled-handle, in which the pressure can be regulated to a nicety by means of two screws. This handle does not allow of any finger pressure being applied to the forcer, through the intermedium of the upper blade; and the latter being T shaped posteriorly, is thereby prevented from going forward with the forcer, owing to the circumstance, that the arms of the T play against the corresponding uprights of the arch of the tunnel (Fig. 1, plate).

The posterior end of the lower blade is soldered in a groove, formed for it the whole length of the floor of the tunnel.

The tunnelled-handle made for me by the Messrs. Weiss is wrought in steel and silver, the ends and floor of the arch being formed of the first material, the remainder of the latter; but silver is not essential for its construction.

I have caused the vesical end of the dilator to be made bulbous (Fig. 2, plate), and have transferred the opening for the urine from the point to the convexity of the curve. The bulbed point facilitates the introduction of the dilator.

The curve should not be too abrupt. The dilator, in fact, should be nearly straight.

I have been trying a variety of forms of forcer. Fig. 3 in the plate represents vertical sections of some of the most useful shapes. As for myself, I prefer the low and broad forcer, it is so perfectly secured against lateral tilting, by resting upon and grasping, as it were, the lower blade at each side of the longitudinal slit.

The narrow forcer requires to be made a little deeper than the broad one, to produce an amount of dilatation equal to the latter. The groove of the upper blade must be very accurately adapted to the upper edge of the narrow forcer, which it should slightly overlap. The two sections of narrow forcers represented in figure 3 (plate) have not been drawn deep enough to show the proportion they should bear to the broad ones.

The Perrève and the tunnel-handled dovetail dilators, are both made by the Messrs. Weiss; but the tunnel-handled instrument is so complete in every respect, that it is the one I recommend.

THE DOVETAIL URETHROTOME CONDUCTOR AND SINGLE-BLADED DILATOR.

A conductor similar in principle to the lower blade of the double-bladed dovetail dilator, forms an excellent director for the urethrotome, the latter being adapted to the single blade by means of the dovetail arrangement (Fig. 4, plate).

If the urethrotome and the conductor are properly fitted to each other, the groove of the latter will pilot the urethrotome to a stricture with precision and safety. The Dovetail Conductor is, therefore, free from the risk incidental to the use of many of the instruments, designed for cutting strictures from before backwards.

The Messrs. Weiss have made a conductor of this description for me. It, likewise, has a tunnelled handle, which is constructed of materials similar to those of the Double-Bladed Dilator. This conductor is of small calibre, being only 1½, 2, and 3 (Weiss' guage), from point to handle. The point may be made bulbous.

In the convexity of its curve, there is an opening to permit the escape of urine into the conducting groove, and thus to indicate when the instrument has entered the bladder.

The urethrotome for the Dovetail Conductor, has, along its lower edge, a male dovetail, adapted for gliding along the groove of the conductor, and of sufficient calibre to prevent it from rising out of the groove (Figs. 5, 6, and 7, plate).

The lower edge of the cutting-blade is also dovetailed, so that when it is sheathed, its dovetail appears to be continuous with that of the sheath (Fig. 7, plate). By this arrangement of the knife, it is maintained in a position, perfectly central, when it is pushed forward to divide a stricture.

In the posterior steel arch of the handle of the conductor, there is a screw, for rendering the sheath immovable, when its vesical end has reached the stricture (Fig. 4, plate).

In order to ascertain whether the stricture has been completely divided from before backward, the knife is to be retracted within its sheath, the screw loosened, and the sheath is then to be pushed forward towards the bladder.

The dovetailed conductor may also be used as a dilator: but, is not adapted for such rapid dilatation, as the double-bladed instrument is capable of effecting. In Fig. 4 (plate), is represented the form of forcer essential for the single blade.

Four forcers, at least, should be supplied with the dovetailed conductor, viz:—Nos. 4, 7, 10, and 13 (Weiss' guage). The increase of each forcer in calibre, from before backwards, should be very gradual, in order that they may the more easily enter the stricture, and not push it before them.

I by no means wish it to be thought, that I consider the single-bladed dilator calculated to supersede the double-bladed instrument. I designed it originally as a conductor for the urethrotome. The idea struck me, however, that if the forcers are shaped as above directed, (Fig. 4, plate[1]), it may, in careful hands, be used as a *slow* dilator, provided the surgeon takes the precaution of holding firmly, both the glans-penis and tunnelled handle, while he is gradually insinuating the forcer into, and dilating, a stricture. For, should he neglect to keep the glans fixed and well-forward, the stricture will recede before the wedge, and he will fail in getting into the narrowed part.

The bulbed vesical end of the dilator can be easily fitted with either a movable long, or a short, gum-elastic guide, by means of a screw arrangement. The bulb being hollowed for the reception of the male screw, attached to the gum-elastic guide. One of Perrève's models has a somewhat similar arrangement.

All the above described instruments are kept in stock by Messrs. Fannin and Co., the Messrs. Weiss' agents in Dublin.

1 The Engravings by the Messrs. W. and A. Oldham, Dublin.

NEURALGIA:

CASES TREATED SUCCESSFULLY BY THE SPINE-BAG.*

By JOHN CHAPMAN, M.D., M.R.C.P., M.S.C.S.,
PHYSICIAN TO THE FARRINGDON DISPENSARY.

THE cure of neuralgia, whether the disease be treated by drugs given internally, or by applications of various kinds at the seat of pain, or by the two methods conjointly, is confessedly almost always difficult, and in a large proportion of cases impossible. The cases reported below have been treated by a method altogether new. By stating each case with extreme brevity, I am enabled to present at one view within a small compass the results of several experiments; and I do this in the hope that they may produce such an impression on the minds of professional readers as may impel them to acquaint themselves with the pathological and therapeutical principles of which these results are an expression. I shall hereafter publish an exposition of those principles, illustrated by reports of cases *in extenso*, and shall then give a full description of the treatment adopted.

1. *Facial Neuralgia.*—T. H., a gentleman, aged 35, who had been suffering during the previous fortnight, requested my advice March 18, 1865. He was in great pain, which had been continuous from the previous day, and which had wholly deprived him of sleep. The pain was chiefly on the right side of the face and head; but during the morning preceding my visit the left side had become invaded. The affected parts were very tender, and somewhat swollen. The head was rather hot, the face flushed, the tongue thinly coated with whitish fur; pulse 92, full and strong. Several medicines prescribed by two physicians in succession had proved of no avail.

I applied a ten-inch spinal water-bag, containing water at 130° F. to the cervico-dorsal region, and shortly afterwards left the patient's room. Within half an hour I returned, when I found him asleep. The treatment was continued for two days by means of heat; afterwards I used ice (at first in the lumbar region), and from the time he first fell asleep he continued free of pain, which has not since returned.

2. *Facial Neuralgia.*—Fräulein S., aged about 25, consulted me February 3, 1867, on account of neuralgia affecting the infra-orbital and dental branches of the trifacial nerve. The pain was not confined to one side of the face, but was sometimes most acute on one side, sometimes on the other; it increased at night, and kept her awake the greater part of each night. She had been suffering in this way for about three weeks before I saw her. Her general health was good. The affected parts presented no trace of hyperæmia.

She was treated by means of ice, and experienced almost immediate relief. After three days of treatment she felt, and slept, very much better; and before the end of the fifth day the pain had wholly ceased. Nearly a year afterwards she told me that it had never returned.

3. *Facial Neuralgia.*—Mademoiselle M., æt. 20, consulted me in August 1867, when she was suffering from acute facial neuralgia, the chief foci of which were the infra-orbital foramen, and the mental foramen of the right side. The extreme pain came on in fits, sometimes at 8 A.M., sometimes at 2 P.M., but between the paroxysms the face continued to ache, and at times the patient had pain at the back of the head. She had suffered in this way about a fortnight before coming to me, and had had several similar attacks during the preceding year.

The treatment consisted in the application of the double columned hot water-bag. The malady was immediately subdued: no distinct paroxysm occurred after the first application of heat; all pain rapidly and completely subsided, and since that date has not returned.

4. *Dental Neuralgia.*—A. W. B., a Russian gentleman suffering from dental neuralgia, consulted me in September, 1867. The malady was chiefly confined to the teeth of both upper and lower jaw, but no particular tooth or teeth seemed to be especially affected. The pain was intermittent, and so severe as to interfere seriously with the patient's daily occupation. No cause of the disorder, which had continued some weeks, could be discovered, and the face so far from showing any sign of hyperæmia over the seat of pain, seemed cooler than normal. In the course of the first day of treatment by means of the spinal ice-bag, the pain was completely subdued; the cold was persisted in for some time, and during the remainder of the patient's stay in England he continued free from suffering.

5. *Dental Neuralgia.*—H. E., female, aged 21, suffering from violent and continuous pain, spreading over the teeth and gums of both the upper and lower jaw, consulted me, January 17th, 1868. The pain was most intense in the lower jaw and on the left side; she had intense headache also. The forehead and cheeks were notably hotter than normal, and she complained of great heat in the roof of the mouth as well as in the gums—which were swollen and sore. During the previous week she had had several teeth stopped with gold: one of them became most especially painful; and there was threatening of an abscess at its root.

The treatment consisted in the application of cold across the occiput, and of heat over the cilio-spinal region—in the first instance separately, and afterwards simultaneously. The pain was speedily and completely annulled; it recurred, and was again annulled by the same method on several occasions. The patient volunteered the statement that, during the application of the heat, her mouth became perceptibly cooler.

6. *Facial and Brachial Neuralgia.*—Mary A. T., æt. 44, first consulted me at the Farringdon Dispensary, December 28th, 1867, when she was suffering from neuralgia of the right side of the head, face, and neck, and along the right shoulder and arm—extending to the fingers. The right half of the tongue was also affected. The pain, which was exactly limited to the median line, was described by the patient—"like as if something is pulling the flesh off the bone, it's so dreadful, and sometimes as if the parts were screwed up in a vice."

She was treated by means of ice applied along the whole spine. She improved immediately and rapidly, and as early as January 15th, informed me that she had not had "a bit of neuralgia" during the whole of the preceding week. Up to this date (February 29th), the pains have not returned.

7. *Intercostal and Hypogastric Neuralgia.*—Miss E., who first consulted me, January 14th, 1865, complained of extreme pain on the right side of the lower dorsal and upper lumbar vertebræ, extending outwards and thence forwards to the right hypogastric region. The pain had continued every day and night, with occasional intervals of three or four hours release from suffering, and had lasted about 20 years. The pain was so distressing and wearing that the patient's strength had become much impaired—especially by loss of sleep, and she was unable to undertake any regular occupation. The only sleep she could get was induced by brandy and narcotics. She suffered also nearly every morning, and frequently throughout the day from nausea, and occasionally vomited "water."

I directed the patient to leave off brandy, opium, and morphia at once and entirely; and treated her chiefly by means of ice along the lower half of the spine. As early as February 14th, the patient was enabled to say to me,—"During the last few nights I have slept throughout the night without being disturbed at all—an experience quite new to me." On the first of the following April she informed me that she had already been many days absolutely free from pain. The nausea and vomiting had ceased; and the bowels had become "open every day—quite a new feature." I have since heard, from time to time, that this patient continues well.

8. *Intercostal Neuralgia.*—A man came to the Farringdon Dispensary, October 21st, 1867, and complained to

* The Spine-bags are supplied by Messrs. Maw and Son, 11, Aldersgate-street, London, and can be obtained from them through the agency of any druggist.

Dr. Drysdale, whose patients I was seeing with him, of acute pain along one side of the chest; no assignable cause for it could be detected, and we regarded it as a case of intercostal neuralgia. I recommended the application of the spinal ice-bag along the dorsal spine twice a-day. "Sometime afterwards," as Dr. Drysdale related to the Harveian Society, "the man returned to the dispensary, looking so delighted," that the doctor "asked him what was giving him so much pleasure, when he replied that the 'ice-bag had done him a world of good: it had taken away all his pain with wonderful quickness.'"

9. *Intercostal Neuralgia.*—Mary B., æt. 51, first seen by me November 27, 1867, complained of intense pain over the right shoulder, between the scapulæ, and along the right side of the chest. During the attacks of pain which came on and went away suddenly, the flesh, she said, quivered and tingled. She felt her body bent down as if she could not move it for fear of the pain.

She was treated by the application of the spinal ice-bag along the lower half of the spine during an hour twice a-day. The patient was surprised to find herself already quite free from pain during November 29th and 30th. Early in December, it recurred very slightly, but on the 18th, she said she remained free from neuralgia, except slight pain in the evening when fatigued by her work; she became much stronger, and was not so "nervous"; by December 28th all pain was gone, and February 26th, when I last saw her, it had not returned.

10. *Chest-Ache.*—October 21st, 1867, I was asked at the Farringdon Dispensary by Dr. Drysdale to prescribe for one of his patients, Maria Williams, aged 22, who was then suffering from continuous aching beneath the right clavicle, together with "dreadful pains" in the head, dizziness, heaviness in the morning, and profuse leucorrhœa—which had lasted several months.

I prescribed the application of a narrow 16-inch ice-bag along the spine during 30′ twice a-day—the bottom of the bag being placed on a level with the 4th lumbar vertebra.

October 26th.—The patient reported that the ice-bag had done her "a wonderful deal of good"; that the leucorrhœa had stopped, and that *all* her head symptoms had vanished. I requested her to persist in the treatment previously prescribed. By November 2nd the pain beneath the right clavicle had quite ceased, and no one of all her other troubles, previously got rid of, had recurred.

11. *Mammary, Ovarian, and Uterine neuralgia.*—H. M., a girl aged 17, who was first seen by me Feb. 24th, 1863, and who was suffering from daily attacks of epilepsy (*petit mal*), complained of extreme pain in the region of the left ovary, which was tender on pressure, and increasingly so immediately before the patient's menstrual periods; also of pain in the right mamma—which was considerably larger than the left, and of "fearful cutting pains" in the womb during menstruation.

I treated this case chiefly by means of iced-water applied along the spine. The result was complete cessation of the mammary, ovarian, and uterine pains; the mammæ became of equal size; and the epileptic vertigo, which had continued many years, ceased entirely a month after the treatment began, and has never recurred.

12. *Neuralgia of the legs.*—I was consulted June 25th, 1867, by Mr. ——, M.P., aged 49, who complained of excruciating neuralgia in the legs. The pain was of the ordinary tearing, shooting, and stabbing kind, sometimes in one limb, sometimes in the other, and affecting one heel almost continuously. This was often so acutely tender that he could not bear to touch the ground with it. As a rule the patient suffered most at night, and could rarely get any refreshing sleep. The malady came on about sixteen years ago, and had recurred at intervals ever afterwards. Until the morning he came to me he had never been free of intense pain for nineteen days. The patient was in the habit of drinking daily about a pint of sherry which I advised him to give up.

The treatment consisted in the application of a spinal ice-bag along the lumbar and the lower half of the dorsal vertebræ. The patient informed me, July 12th, that "practically speaking" he had had no pain since he began the treatment, and that he had slept well. I advised perseverance with the ice, and abstinence from wine. The patient wrote to me August 21st, "I continue to receive great benefit from the ice application, and shall continue it." The pain afterwards recurred in a mitigated form, but was greatly subdued by the ice, and, I incline to believe, would be quite cured if the patient would wholly abstain from wine.

13. *General Neuralgia.*—June 22nd, 1865, I was consulted by Lord ——, on account of neuralgia affecting different parts of the body: the walls of the chest, and the lower extremities were chiefly involved. The attacks generally came on suddenly, and lasted about fifteen hours, sometimes longer. The pains were of an acute, stabbing, and seemingly spasmodic character, and were often brought on by vigorous, muscular exercise, especially deer-stalking, which his lordship is very fond of, but which his attacks either cut short or prevented him from indulging in.

I prescribed the application of ice along the spine, and five grains of citrate of iron and quinine during a few days at a time occasionally. When I saw the patient again, April 27th, 1866, he informed me that he had applied the spinal ice-bag as directed during several weeks at a time at three successive periods since he consulted me. He declared himself so greatly improved that he had been quite free from his malady for long periods together, that when it had recurred the pains had been comparatively slight, that he could resume violent exercises, including deer-stalking, without bringing on an attack, and that in his opinion, had he continued the treatment regularly for a longer time he should have been completely cured.

14. *General Neuralgia.*—Hannah E. complained to me January 4th, 1868, at the Farringdon Dispensary, of great pain in all the four limbs, but most especially in the fingers and toes, and in the left side over a spot about the size of half-a-crown; of headache each morning; of "dreadful" back-ache; and of excessive irritability of the bladder, involving the necessity of urinating about every five minutes.

She was treated by the application of the lumbar ice-bag 90′, twice a-day. Within a week the pain in the limbs was almost wholly gone. By the 15th of January it, as well as her headaches, had quite ceased; her back was much better; and she was obliged to micturate only about every hour. On the 5th of February she reported herself free from every pain on account of which she had consulted me, and the irritability of the bladder was so much lessened, that she was only troubled with it at intervals of about 90′.

OUGHT DEGREES, OR OTHER PUBLIC CERTIFICATES OF SCIENTIFIC OR PROFESSIONAL ACQUIREMENTS, TO BE GIVEN TO ALL WHO PRESENT THEMSELVES FOR EXAMINATION AND STAND THE TEST?

By CHARLES DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.

In an admirable address on Medical Education and the Examining Boards, delivered at the Medical Teachers' Association, January 20th, 1868, Mr. Simon has proposed, for the first time in my experience, a question to the Medical Profession and the general public, which is, I believe, destined to receive much attention for some time to come from all who desire the advancement of learning. If we consider the tendency of modern opinion, we can easily observe, that the same habits of thought which have of late years led to the freedom of trade, and the abolition of protection of industries, are leading gradually to the same conclusions in respect to those questions which are of so much higher importance to human welfare, than even the free exchange of the material products of human toil.

The proposition that the public, or employer of labour, should have the right to seek for the best and the cheapest

article, irrespective of the country wherein, or the manner in which that article has been produced, is now an axiom generally received, in as far as the products of labour are concerned; but, hitherto, custom has willed that the extension of this principle shall not proceed so far as to admit all persons of sufficient education to examinations for degrees, either in general science, in medicine, or in theology. It has been, and is still the custom, to demand from the candidate for Medical degrees, certificates of all kinds, often vexatious and irrational to a degree, which we could scarcely believe could exist in so enlightened an age as this, as to attendance on the lectures of some qualified teacher, and even, in many cases, only the teachers of some particular school are recognized, and this practice is by no means confined to students under the age of 21; but is kept up for all students, even for men of 30, 40, or 50 years of age, who can in no way be supposed to be wanting in desire for their own interest, or in the wish to acquire knowledge as quickly and as thoroughly as possible. The consequences of these mistaken regulations of class-attendance, enforced by most of the colleges and universities of this country is that, after a student has passed through three or four years of lectures at a *school*, it seems very hard to reject him at his examination period; and hence, the standard of excellence required by the examining boards in the country are, almost without any exception, far too low. And, for this reason, I am quite of the opinion of Mr. Simon, that "if I could assume the thorough efficiency and disinterestedness of our examining boards, I may say for myself, that I should be well satisfied to look to the stringency of the examination, as a substitute for all regulations whatever, and would admit to be examined, with a view to registration, anyone who had arrived at the age for undertaking civil responsibilities," *i.e.*, the age of twenty-one years. In fact, this view of the question is one which was strenuously advocated for a long time by the illustrious statesman, Baron Wilhelm von Humboldt, and has also received the approval of the master thinker of the age, Mr. J. S. Mill, in his essay on Liberty. The last-named writer, indeed, proposes the system of examination, as the only one which the State should sanction with regard to children. Thus, he proposes that an age might be fixed at which every child should be examined, to see whether he (or she) were able to read; and if the child proved unable, it should be put to school at the parent's expense. Once in every year the examination should be renewed, he adds, with a gradually extending range of subjects, so as to make the universal acquisition, and what is more, retention, of a certain minimum of general knowledge, virtually compulsory. The examination in the higher branches of knowledge should be entirely voluntary. Wilhelm von Humboldt was of opinion, that degrees, or public certificates of scientific or professional acquirements, should be given to all who present themselves for examination, and stand the test, but that these certificates should confer no advantage over competitors, other than the weight which may be attached to their testimony by public opinion. Mr. Mill quite endorses this opinion; and it remains for us to take notice of some exceptions which have been taken to the proposal. It has been urged by persons of great experience that, if medical degrees were thrown open to all over the age of twenty-one, there would be some persons gifted with an admirable memory, and with a rapid power of acquiring knowledge, who would from these facts be enabled easily to take any such degree by merely studying, or what is called cramming, for a few months previous to examination, rapidly forgetting after the examination all their rapidly and ill-digested mass of knowledge. This is certainly the best argument for maintaining the present state of matters, which has, as far as I know, been adduced; but I believe the difficulty would be easily enough avoided by enforcing a very different style of examination from those which now obtain. Thus, I do not believe it would be possible for a student to be able to dissect well, unless he had given a considerable time to the subject practically; and, in the same way, it would be almost impossible for him to make a good diagnosis in disease of the chest, without having spent much time in the wards of an hospital. But, even if a man of great genius *were* able to acquire, in the short space of a year, all the knowledge requisite for passing a thoroughly good examination, it appears to me that the public would in this be the gainers, since they would thus have obtained, at small cost, a highly accomplished servant. And, after all, if we are driven to confess that examinations, however well conducted, can never attain the desired end of ascertaining the capabilities of a candidate for the degree of physician or surgeon, we must also confess that the present system is far more inadequate to that end. What? an hour spent in the library of the College of Surgeons, with four examiners, shall be considered sufficient, added to the certificate of attendance at some qualified teacher's classes, to test the abilities of a medical practitioner. It is a farce. What, again? must the unfortunate medical student continue much longer to have to think whether the school he attends at this part of the island may or not have its certificates accepted by those of some other locality, where he is fated to take his degree. The whole of these regulations are so vexatious, and so ill-constructed, that I cannot in any way see a path out of the perplexity, except by adopting the proposition of Humboldt, Mill, and Simon, and throwing open our Medical degrees to all candidates over the age of 21 years. The only two examining boards which have hitherto at all comprehended this problem, are those of the University of London, and of St. Andrews; but neither the one nor the other of these bodies has, as yet, dared to take the bold and final step, which, I hope, *both* may ere long adopt. For example, the University of London requires of Candidates for its M.B. examination, that they shall have (which is excellent) passed a matriculation examination; but, next to this, which I hold is an error, that candidates shall have been engaged in professional studies four years subsequently to this early examination: *one year to have been passed in the United Kingdom.* Cui bono all of this. If the University of London would but cast off these latter vexatious conditions, and keep up the stringency of its examination tests to the highest point, it would soon raise the standard of medical education in this country, and, instead of giving, according to Mr. Simon, twelve degrees in a year, it might give 200 equally good ones. The present degree evidently cannot be taken by persons already in practice, because they would have to wait for four years before taking it.

I will not dilate upon the folly of supposing that, because we can certify that students are bodily in the classroom, that therefore they are attending to the lecture. In those days of cheap books and libraries, it is certainly rather too much to require that students should have to listen over and over again, *usque ad nauseam*, to the very words which the able lecturer, perhaps, has just written in his text-book. The student will soon find out what lectures are absolutely necessary for him, and what subjects he can learn better from books. In all that I have said, I in no way interfere with the discipline which schools may think proper to enforce upon their students. These, like home discipline, may be, and are in some cases, highly necessary in the case of young persons; but the main point in the matter we are discussing is, that the best article—*i.e.*, a highly educated medical man, should be obtained in the quickest and most efficient manner, and I therefore conclude by asserting that "degrees, or other public certificates of scientific or professional acquirements, should be given to all who present themselves for examination and stand the test."

CASES OCCURRING IN THE PRACTICE OF JAMES MARTIN, F.R.C.S.I., L.K.Q.C.P.

CASES OF PUERPERAL CONVULSIONS.

JANUARY 28th, 1861, I was called at 1 A.M. to see Ann Rielly, æt. 24.

Being in the ninth month of pregnancy she had false labour-pains the previous day, for which she remained in bed. Early in the previous night she was disturbed by a drunken squabble at her door; her head, which had ached all day, became intensely painful, and when I was sent for, she had been just seized with a violent epileptiform convulsion.

On examination I found the os uteri open to admit the top of the finger, but no uterine action. I immediately took ten ounces of blood from arm, when the convulsions ceased, but she became pallid, and it was evident that further abstraction of blood would do harm. I had a fetid turpentine enema administered, and gave a stimulant draught of chloric æther and sp. ammonia; the convulsions returned in about half-an-hour, but ceased on the enema acting copiously.

In the morning she was still insensible; slight convulsive movements occasionally; the muscles firm and rigid; pupils dilated and sluggish; cheeks flushed, and head hot. I applied six leeches to temples, and gave a cathartic bolus of calomel and jalap. In the evening the same state continued, and the bolus not having acted, I administered one drop croton-oil, and four grains of calomel, had the head shaved, and a strap-blister over the entire scalp.

Seven A.M., January 29th.—Same state, lying prone, with occasional convulsive paroxysms, more or less violent; perfectly insensible to external objects; pupils dilated and inert; bowels freely moved three times during the night; os uteri enlarged to size of half-a-crown, but no evidence of labour having set in.

Ten A.M.—I was sent for hastily, labour had set in violently about an hour before, and it having been a breech presentation, I found the body delivered, the head remaining in the vagina. I speedily extricated this, the placenta was soon expelled, followed by a smart dash of hæmorrhage; the uterus, however, contracted well and quickly. Immediately after the convulsions returned in violence, but the pulse being soft and compressible, I ventured to give half a drachm of tincture of opium, after which they ceased, and she fell into a stertorous sleep; the pupils were still dilated, but became actively sensitive to the action of light. Sinapisms were then applied to the legs, which roused her considerably, and, in speaking to her two hours afterwards, she seemed conscious.

In the evening she was more conscious, turned her eyes towards any person addressing her, and evidently heard distinctly.

Hyd. i. crœt. gr. ij. 3tia q. hor., her head dressed with ung. hydrarg.

Jan. 30.—I found her conscious and able to reply to questions, but looking vacant and wildly; pulse 96; bowels acted during the night; takes broth and arrow-root. Cont.

Evening.—Continues to improve.

Jan. 31.—Restless night, pulse 110, firm and sharp; lochiæ present. No tenderness on pressing over the abdomen; headache; bowels acted twice. Intermit hyd. i. crœt. + affricen. axil. unguenti hydrarg. drachmâ ter indies.

Evening.—Had two slight convulsive fits during the day, but is now quite sensible; skin moist; pulse 110, sharp and firm; has had no sleep; breasts tumid; lochia still present.

The child having died, the breasts were drawn; bowels acted once freely during the day; ordered pulv. Doveri. gr. vi. Hyd. i. crot. gr. iij. statm. Affricen. Mammæ. unguento. Ex Belladonna 3j. Axungiæ 3iij.

Feb. 1.—Had a good night; free perspiration; pulse 84, soft; breasts soft; gums tender; quite clear in answering questions. Interm ung. Hydrarg.

Feb. 2.—From this day her convalescence was steady and progressive.

June 3rd, 1863.—Alicia Hickey, æt. 23, first pregnancy about the end of the seventh month, was seized with violent convulsions. I saw her within half-an-hour of the first seizure, and finding all the vessels of the scalp turgid, and the pulse full and firm, took some blood from the arm, how much I could not say in consequence of her struggles not allowing of its being collected, but sufficient to make an impression on the pulse. The convulsions ceased, but she remained insensible and stertorous. The os uteri was dilated about the size of half-a-crown, but no uterine action. I put a drop of croton oil on her tongue, and left a woman with her. On returning in about two hours I found, that just on my arrival the bowels were actively moved, and, at the same moment, the fœtus, and placenta, were expelled together. The child lived for two days; no hæmorrhage followed. Insensibility continuing, I applied over the scalp which had been shaved in the meantime, a strap blister, and gave beef-tea frequently. Next morning I found her conscious and able to take her food; the blister rose well, and she made steady progress to convalescence.

WOUND OF SCALP.

Jan. 20, 1865.—A car-driver was thrown from his car near my house, inflicting a wound about 8 inches long, and throwing down a large flap, under which could be seen great part of the temporal muscle. My son, a pupil, at present attending Mr. Syme's class in Edinburgh, being at home, went to where the occurrence took place, but alarmed by the extent of the wound, sent for me. I found on my arrival that he had cleaned out the flap; mopped all the interior of the wound with oil, containing 1·30 part of pure carbolic acid, and brought the edges of the wound into as close apposition as their bruised state admitted. We then applied some adhesive straps to retain it, kept pressure for 10 or 15 minutes with the hand over the flap to prevent any oozing of blood, which might be retained under it, and finally dressing the wound with strips of lint dipped in the same oil, applied a double-headed roller carefully. He then drove himself into Waterford, a distance of ten miles, the day being cold and frosty, and became a patient in the Leper hospital of that city.

Dr. Cavet, under whose care he has been, informed me that the whole flap adhered, and the entire wound healed without it being necessary to change the dressings, and without one drop of pus having been formed.

Hospital Reports.

MERCER'S HOSPITAL.

INFLAMMATION OF THE SCROTUM ENDING IN EXTENSIVE SLOUGHING.

By Mr. J. MORGAN, F.R.C.S.I.,

SURGEON TO MERCER'S HOSPITAL; PROFESSOR OF SURGICAL AND DESCRIPTIVE ANATOMY, R.C.S.I.

DIFFUSE INFLAMMATION OF THE SCROTUM RUNNING INTO MORTIFICATION.

Having met with some instances of acute inflammation of the scrotum running rapidly into mortification and sloughing occurring in persons of low vitality, and under special exciting causes, the following case, from my hospital notes, may not be uninteresting as an illustration:—

R. H., a thin man, aged 56, hitherto healthy, a hard worker at his trade of painter and general jobber, and of extremely penurious habits, was admitted to hospital, Wednesday, at twelve o'clock; he states that he had been particularly hard worked during the previous week; that he had not taken any meal at midday or dinner; had been a good deal exposed, and wore a pair of new *hard trowsers* the previous Saturday.

On going home that evening he first felt pain in the upper part of the thighs, and some tingling of the scrotum, but hardly enough to attract particular attention.

On Sunday the scrotum began to swell mostly at the depending parts; there was no increase of pain, but more a sensation of weight, and it was not till Tuesday that any great pain was felt, or that he was obliged to stay quiet. He

describes the scrotum as having been now red; the pain was tingling; he had no difficulty in passing water, the chief inconvenience being the sensation of weight.

On admission on Wednesday the scrotum was very much swollen, as was the penis; the scrotum had a soft feel, showed a small slough, and there was a considerable slough on the penis, ash coloured, and moist; the perineum was perfectly normal, the swollen scrotum being abruptly marked off; there was great prostration of strength, the pulse weak and feeble, 100.

A catheter was introduced as a precautionary measure, without difficulty.

Free incisions were made into the scrotum, which was deeply sloughed. Stimulants freely administered, bark and ammonia mixture ordered every three hours; the parts were dressed with camphorated spirit, and surrounded with cotton; the scrotum being well supported.

Thursday.—The slough of penis had considerably extended; the general swelling diminished; two additional incisions, deep and free, were made at the root of penis and scrotum; general symptoms rather improved; treatment continued.

Friday.—Slough on penis rather extended; condition of scrotum improving, and the swelling not quite so marked; treatment continued, with a free supply of stimulants; spirits in punch, and flip, &c.

Saturday.—The entire prepuce and much of the skin of the penis is now sloughed; the scrotum is improved and the sloughs are beginning to separate

Treatment and stimulants continued.

Tuesday.—The slough of penis extending; an erysipaletous blush is now showing itself round the thighs and lower part of belly; pulse 120, and strength rapidly failing. The patient died during the night.

A post-mortem examination could not be obtained, but, as far as could be learned by local inspection and examination, the testes were lying in a slough, the entire integument of the penis was sloughed away; the urethra was healthy and perfect, and the scrotum altogether disorganised.

In this case the man attributed the first commencement of the disease to the "hard trousers," and, besides, he had been working with unusual effort—standing cleaning windows; the rapidity of the sloughing process, and the tendency to spread, till the penis was thoroughly denuded, was well-marked.

I have met with some cases very similar to this one, but none of them fatal, occurring very much under the same circumstances in dealers and others going from fair to fair, where the "best trousers" were put on, which, being hard, were always looked on as being the exciting cause. In these the sloughing process was very rapid—one man, aged 60, was taken into hospital, January 13, the entire scrotum being pulpified by sloughing: he had walked to a fair some fifteen miles off, and on the second day after doing so, was admitted in this condition; the parts healed with great rapidity, so that he was discharged, cured, on February 1, a period of eighteen days only being required.

Another younger, but delicate man, aged 35, under much the same circumstances, was admitted June 7, and discharged on the 28th, cured; the closing-in taking place with great rapidity, a period of twenty days only being required.

In general, the cases are seen when the entire scrotum, or the greater part, has absolutely been in a state of slough, and once the slough is about separating, the camphorated spirit acts most beneficially as a mild stimulant. I believe these cases are met with in the country more frequently than is generally supposed.

ST. GEORGE'S HOSPITAL.

A YEAR'S SURGICAL PRACTICE.

(Continued from page 133.)

Diseases of the Nervous System.—Under this head are comprised diseases of the cerebro-spinal system and of its coverings.

Two cases of epilepsy occurred; one in which there was an old depressed fracture of the skull; in the other the patient was burnt. These are the only two instances in which the disease manifested itself during the patient's stay in the house; the other cases in which accidents were ascribed to epilepsy have not been entered here.

There were six cases of delirium tremens, occurring in patients who had met with accidents; two died. Two cases of hemiplegia are entered, and five of disease of the brain; these latter were probably due to some chronic inflammation of the brain-membranes, and occurred in patients who had met with accidents: the symptoms were relieved by purgation, low diet, and the iodide of potassium or bichloride of mercury. One case of mania is recorded. It occurred in a young woman who had been admitted with erysipelas of the scalp and face.

One case of infantile paralysis and three of partial paralysis, with one of sciatica and six of neuralgia, complete this class of cases.

Diseases of the Skin and its Appendages.—These present us with a very numerous set of cases, which it is impossible in the present work to consider in detail; such, however, as are of especial interest will be cursorily touched upon.

Besides 26 cases of eczema, we find 15 cases entered as rupia; under these are included several instances of rupial ulcer. They rapidly improved under calomel vapour-baths. In some instances these could not be borne, and the mineral acids, especially the dilute nitro-muriatic with bark, and sarsaparilla, or cod-liver oil, were substituted. Iodide of potassium was also used: of this drug Mr. Ring writes—"Given to patients in a low and cachectic condition, in doses of ten grains, three times a day, it was found that they rapidly improved and increased in weight." A woman aged 37, whose limbs and face were more or less crusted with rupial scabs and ulcers, and the alæ of the nose partly eaten away, died from exhaustion. Cod-liver oil and syrup of the iodide of iron were administered, and for some three weeks she appeared to be doing well, the scabs fell off in numbers, and the ulcers commenced healing; calomel fumigation was also employed: but soon after this, the little strength she had gained began to decline, the healing process was arrested, the ulcers became foul, emitting a fetid odour, and in spite of stimulants she sank exhausted. The body was excessively emaciated. The lungs were œdematous and anæmic; the liver was fatty, and in an early stage of amyloid degeneration; the other organs were natural.

Psoriasis was treated with the liquor arsenicalis, or bichloride of mercury, and bark. A case of psoriasis guttata unaffected by this, improved under calomel-baths.

Two cases of lupus non-exedens and one of lupus exedens came under observation. The former were much benefited by the administration of cod-liver oil and the arsenical solution, with the topical application of an arsenical paste; the latter persistently recurred after extirpation by the knife. The patient, a woman aged 30, had suffered five years previously from circum-orbital pain; this was followed by a rodent ulcer of the eyebrow. The diseased surface was removed by the knife three years subsequently, but had since reappeared. When admitted, there was an elevation of thickened tissue extending from the root of the nose to the scalp. On the left of this the forehead was depressed and seamed with white scars, which extended from the roots of the hair over the orbit (which was obliterated) to the cheek. Just above the centre of the malar bone was a small wart-like excrescence, and external to this a patch of ulceration, with red, sharply-defined edges. She complained of sharp pain, which extended from the root of the nose and seat of ulceration to the vertex. An incision was made down the middle line of the forehead from the roots of the hair to the nose, and the integument dissected outwards from the bone for about an inch and a-half; the ulcerated surface was cut out, and the malar bone

exposed; its surface being somewhat softened, it was scraped away.

On the second day nitric acid was applied to the exposed bone, and rest insured by a morphia draught at night. The wound almost healed in a week, and she was made an out-patient, but a third operation afterwards became necessary.

Two cases of ecthyma occurred in syphilitic patients; in one case calomel vapour-baths, and in the other syrup of the iodide of iron, with cod-liver oil, produced the most beneficial effects.

One hundred and fifty-three cases of ulcer of the leg were admitted. Nine were attacked with phagedæna, and in three instances the extensive sloughing necessitated amputation, and death ensued.

Six cases are entered under the head of cancerous ulceration, in the form of epithelioma. In four of these the diseased mass was extirpated. In one instance the patient, a man aged 61, would not submit to an operation; he had an epithelial growth on the left ring-finger, with an enlarged gland at the bend of the elbow. Acetic acid was applied, and the surface became more healthy. In a case of epithelioma of the lip, the disease was removed by an elliptical incision. In another of the face, the knife was also employed. A large fungoid growth surrounded by unhealthy ulceration occupied the left cheek; and the whole face was covered with puckered cicatrices, as though from a burn. The whole of the diseased mass was cut away. The incision extended from the middle line almost to the angle of the jaw, and went down to the bone. Some suspicious points were touched with the actual cautery, and the whole was covered with chloride of zinc paste. The sloughs separated, and he was discharged with the wounds almost healed. One case of epithelioma of the leg proved fatal from exhaustion; the patient was admitted in a dying state.

The penis was affected in two instances, and the labium in one. In the first cases the disease was removed with the écraseur, in the latter with the knife, and in it the bleeding was effectually arrested by means of the twisted suture.

Sixteen cases of tumour were admitted; viz., six fatty, six sebaceous, one encysted, and three malignant. The fatty and sebaceous tumours were all successfully removed. The former were found on the neck and upper extremities, with one in the labium; the latter in the scalp and face. One case of encysted tumour is recorded. The patient had been an in-patient in 1866, the tumour had been punctured and freely laid open, and then was made to suppurate by the introduction of a silver wire. She was in a weakly state when admitted, but the tumour had almost disappeared. Three cases of malignant disease were admitted. One occurred near the lower end of the femur, another in the glands of the axilla, after the removal of a tumour from the hand; both were discharged at their own request. The third was a case in which a mole assumed a malignant aspect. It occurred in a woman aged sixty-two, in whom a mole had existed on the right arm from infancy. Of late it had been increasing in size, and caustic had been applied, which caused it to ulcerate. It presented a fleshy appearance, was hard, red, and shining, and occasionally bled. It was removed. Under the microscope it was found to contain neucleated cells, some of them of large size, others elongated, and filled with granular matter.

Four cases of carbuncle were admitted. They were treated by incisions, with generous diet and tonics. Three boils, three cases of œdema, eight of onychia, in two of which the nail was removed, and two of corns and bunions, call for no comments. One case of conical and ulcerated stump, in which amputation was performed, terminated fatally from pyæmia. Three others were benefited by treatment.

One case of elephantiasis of the leg, that had existed for eighteen years, proved fatal after amputation.

(To be continued.)

SURGICAL SOCIETY OF IRELAND.

JANUARY 31, 1868.

Mr. COLLES in the Chair.

(Continued from page 193.)

CASE OF STRANGULATED INGUINAL HERNIA, TREATED ACCORDING TO PETIT'S METHOD.

By MR. J. H. WHARTON.

IN the course of the Session 1866-67, I had the honour of making a short communication to this learned Society, on the subject of operating for "Strangulated Femoral Herina, according to Petit's method." The communication will be found amongst the records of this Society, and is published in THE MEDICAL PRESS AND CIRCULAR of 5th May, 1866. The special object I then had in view, was to have ascertained the opinion of the Society, as to the advisability, or otherwise, of opening the sac. I alluded to the part which Professor Hargrave—who was the first to introduce this question to the consideration of the Society—had taken in the discussion which ensued upon his paper, as reported in the 29th Vol. of THE MEDICAL PRESS. Mr. Luke's statistical accounts, as also those enumerated in a communication published in the 32nd Vol. of the *Dublin Quarterly Journal*, by Mr. Maurice H. Collis, testify strongly in favour of not opening the sac. These facts, as well as the opinions of surgeons of eminence, Sir A. Cooper, Sir Chas. Bell, Bransby Cooper, Laurence, Key, and Luke, were noticed in my communication, as being more or less strongly in favour of the proposal of Petit, who made, however, some exceptions to the operation, amongst which may be specified gangrenous intestine, the presence of foreign bodies in the intestine or hardened scybala. Mr. Bryant in his communication, published in the 2nd Vol., 3rd Series, of Guy's Hospital Reports, for the purpose of proving the great value of this operation, as shown by his statistical returns, does not make any exceptions but one, to the method, and that is, where the intestine is ruptured.

My object in addressing the Society this evening, is partly in consequence of a desire to answer a question put by the deservedly lamented Dr. Banon, upon the occasion I read the paper referred to, but which at that time I could only respond to theoretically; and partly to reply to a query privately and incidentally asked, on a late occasion, by Mr. Fleming —"Could the sac be retained in the abdomen?"

The former was to the following effect—"Should the recommendation of the operation be confined to femoral hernia?" I replied in the negative, or rather submitted that the *rule* should apply to all cases of strangulated hernia. A case at present under my care will enable me to answer the question more authoritatively. A man named Patrick Mullen, was admitted to the Meath Hospital, under my care, on Sunday the 5th of the present month, on account of strangulated inguinal or scrotal hernia, at the left side. His age is 64, his occupation a car-driver; he had recently met with an accident which injured his side, and for which he was under medical advice elsewhere, and was, moreover, suffering not a little from bronchitis. A hernia had existed for, "he did not know how long" to use his own words, but the strangulation was not of longer duration than 24 or 26 hours. The taxis having failed, herniotomy was had recourse to. When the sac was reached, search was made for the stricture, and when found, divided, though not without difficulty. By patient and gentle pressure upon the tumour, I had the satisfaction of finding a diminution of its bulk; and this was quickly followed by the return of the intestine. The sac, also, was made to follow with ease; and was retained in the abdomen, so long as I kept up pressure on the external ring, and not otherwise. I mention this in reply to Mr. Fleming. This man is now convalescent, notwithstanding the unfavourable conditions as to age, occupation, his recent accident, and, above all, his bronchitis. To these I might add other drawbacks which he had to encounter subsequently to the operation; for instance, severe diarrhœa, a not unfrequent cause of death after operation. *No aperients were administered.* And the fact of his having on the second night after the operation, got out of bed. This case I do not advance, as sufficiently comfirmative of the expediency of the non-opening of the sac in strangulated inguinal hernia, though it is a proof that it may be done, at all events, with impunity. But I have further evidence to adduce—namely, a case in which Mr. Macnamara operated on in September last, and in which he kindly acceded to my proposal to spare the sac, and with the best results. These are the

only two cases in which I have had an opportunity of witnessing the operation without wounding the sac. So far as they go they are, I think, satisfactory evidence of the reasonableness of the reply which I gave to the question of Mr. Banon, whose untimely removal is still so fresh in our memory. As to the general question of the opening, or the non-opening of the sac, I would be very happy, indeed, to have the opinion of the meeting. I have only to add, sir, in conclusion, that I have operated in femoral hernia since my paper was read without opening the sac, as have also some of my colleagues, Mr. Porter more recently, and with full success.

Mr. CROLY said he had operated several times for strangulated hernia, and had seen many operations performed by his colleagues; and the point he had made up his mind on was this, that if the hernia were a recent one, it was a good rule not to open the sac, when they were certain that there were no adhesions to prevent the gut going back. On the other hand, if the hernia were an old one, and bands of adhesion had been formed, the rule ought to be to open the sac. As he had operated lately on a case of strangulated hernia, he would reserve any further observations on the subject until he came to state the particulars of that case.

Mr. E. HAMILTON asked Mr. Wharton whether, when he did not open the sac, he experienced much difficulty in coming at the stricture?

Mr. STAPLETON said his experience was, that there were a number of cases in which strangulation took place within the neck of the sac itself. He had seen the parts fairly divided, and still it was found impossible to press the intestine into the abdomen, and the strangulation remained. It was not always easy to know the state of the intestine. If the strangulation were in the neck of the sac, the very strangulation itself might be pressed back into the abdomen. He had seen cases where everything seemed to pass off very well at the time of the operation; but on a post-mortem examination afterwards, it was found, that the intestine was absolutely strangulated by the neck of the sac itself.

Mr. FLEMING had operated in cases of strangulated hernia, but always by opening the sac. In the Richmond Hospital, situated in a locality where there were a great many cases of hernial affections, the average number of strangulated herniæ was extremely limited. He would exaggerate if he said the number of such cases, presented at Richmond Hospital, averaged four in the year. That was a small number, comparatively speaking, when the amount of the population was taken into consideration. As to the opening, or not, of the sac, all were familiar with the rule mentioned by Mr. Croly as regards recent and old cases of hernia. Great interest attached to the case brought forward by Mr. Wharton, as being one of inguino-scrotal hernia. It was a matter of much practical value to hear that in such a case the mode of treatment adopted had been successful, the sac being returned into the cavity of the abdomen. In cases of inguino-scrotal hernia, the hernia was necessarily of lengthened duration; the hernia very rarely passed down quickly from the inguinal canal into the scrotum; there were generally connections of the sac in the scrotum in such cases which it was not easy to detach; and to return the sac into the abdomen under such circumstances must be difficult of accomplishment. He confessed he would be apprehensive of mischief resulting from the return of the sac in a case of inguino-scrotal hernia into a cavity so sensitive as that of the abdomen. There was great interest, therefore, attached to this case from the fact of a large scrotal hernia going into the abdomen without opening the sac, and accompanied by the sac, without any injury resulting therefrom.

Mr. STAPLETON observed that in cases of umbilical hernia he had divided the stricture, and did not consider it necessary to return the sac. The intestine was returned, but there was a great advantage in not returning the sac.

Mr. WHARTON, in reply, said he had merely brought forward the case to answer a query put by the late Dr. Banon, inasmuch as at the time the question was asked, he had had no experience of operations for inguinal hernia by Petit's method. Previously, he had always opened the sac, but having seen these two cases in which an opposite method was pursued, he thought it right to bring them under the notice of the Society. The one operated on by Professor Macnamara, was a case in which strangulated hernia had existed for a considerable time, he did not open the sac, and the case turned out well. The other was a case of his (Mr. Wharton's) own, and the patient was now convalescent. He agreed that if the stricture were situated within the sac, the surgeon was bound to open it. As to Mr. Hamilton's question, he thought the difficulty was greatly lessened by operating without opening the sac. In one case of strangulated hernia, in which he had operated after dividing what he believed to be the stricture, he found the hernia would not go back into the cavity. Mr. Porter, who assisted him, then found that a band existed higher up, and this being divided, the hernia was easily returned. Mr. Fleming had rather misunderstood him. He appeared to be under the impression that the sac was retained in the abdominal cavity. What he stated was that he could return the sac into the abdominal cavity, and keep it there as long as his finger remained on the ring, but when he removed his finger it came down again.

STRANGULATED HERNIA.

Mr. CROLY said he admitted a poor woman named Dunne, aged 66 years, into the City of Dublin Hospital on the 16th of January. She had been vomiting for some days, and had no motion from the bowels for weeks. On examining the groin he observed a tumour parallel to, and beneath Poupart's ligament. It measured three inches in the long axis and two inches from above downwards. The patient said she first noticed the "lump in her groin" three years ago after a fatiguing walk. It was always down, but a week previously to her admission into hospital it got suddenly larger, as she lifted down a loaf of bread from a high shelf. The lump gave her no annoyance, and was not tender to the touch; she never wore a truss, and had naturally costive bowels. The pulse was not quick, and the countenance did not present the usual hernial aspect; the abdomen was distended, and she complained of a colicky pain near the umbilicus. Her stomach was sour, and she was thirsty; lime-water and milk was ordered as drink, and pieces of ice to relieve the thirst. A turpentine enema was administered with O'Beirne's long tube (which was passed up its full length without any difficulty or obstruction), but came away at once without any fœcal matter. He satisfied himself, after a very careful examination of the tumour, that it came down through the femoral ring, though presenting the shape of an oblique inguinal hernia. A consultation was held a couple of hours after the patient's admission into hospital, and it was decided that an operation should not be performed, as urgent symptoms were not present. Ice was applied to the tumour, and the injections repeated. There was no return of the vomiting, from the patient's admission into hospital, until the 17th inst., when she rejected some greenish coloured fluid. On the 18th inst., as there was no motion from the bowels, and the tumour could not be reduced by taxis, it was decided, upon consultation, that an operation should be performed.

The patient was chloroformed, and the usual operation for femoral hernia performed—the sac was not opened. Poupart's ligament was first divided and then Ginbernat's. Careful pressure was made on the hernia but it could not be reduced; as all constriction was divided the wound was closed with sutures.

There was no return of the vomiting until the 20th inst., and no diminution in the size of the hernia. The bowels were not freed; another consultation was held, and it was decided to explore further the hernia, by opening the sac, and if it could not be reduced to make an artificial anus; accordingly, the single incision was converted into an inverted ⊥, and the flaps being dissected up, the sac was carefully opened: the intestine was dark-coloured and a large piece of omentum was closely adherent to its external surface.

No constriction could be felt elsewhere, but one portion of the gut was found to be gangrenous, and gave way under the finger; the piece was removed and the edges stitched to the external wound. A large quantity of liquid fæces escaped through the artificial anus; the patient was removed to bed—hot applications were applied to the extremities—wine, beef-tea, and opium given, and ice to relieve the thirst; poultices were constantly applied over the artificial anus, and the parts were frequently washed with a solution of carbolic acid.

The patient expressed herself as much relieved, and the abdomen re-assumed its natural size. She took plenty of nourishment, and had a nutritive injection thrown into the rectum every third hour. She gradually sank, and died on the 28th inst., fourteen days after admission. I made a post-mortem examination in the presence of the class, assisted by my colleague Dr. Hewitt.

There was a double coil of the ilium found in the *femoral ring*, and a large gangrenous mass of omentum to its outer side—the small intestine near its termination was congested, and there were bands of lymph gluing the intestines together—

the vermiform appendix *adhered* to the small intestine by its tip; the pelvic fascia and peritoneum on the bladder presented a highly vascular appearance, and there was a large quantity of purulent matter in the pelvic cavity. The transverse colon was doubled on itself and passed down near the left inguinal region. The cœcum contained some scybala and was moderately distended with flatus.

Mr. EDWARD HAMILTON asked whether the bowels acted after the operation, for so far as his experience went, the most frequent cause of death after the operation for strangulated hernia, was atony of the intestine. It not uncommonly happened in these cases that the intestine did not recover its tone.

Mr. RICHARDSON said that many surgical writers allude to the fact just mentioned by Mr. Hamilton, that it does not follow if the stricture is removed, the natural peristaltic intestinal action will be resumed. Thus, the nipped portion of bowel, although not gangrenous, may be so injured as to be incapable of recovering its function. Again, peritonitis, limited to a small length of intestine not engaged in the hernia, may cause paralysis of the subjacent muscular structure, and not allow anything to pass through this portion of the intestinal canal. He (Mr. Richardson) operated upon a case of strangulated femoral hernia, released the bowel from its stricture, and, notwithstanding that there was scarcely any appreciable tenderness of the abdomen, the symptoms of strangulation persisted, and death quickly followed. In that case, on opening the abdomen, he found several inches of the small intestine, some distance from the portion of hernial bowel that had been nipped by the stricture, intensely inflamed with small gangrenous spots here and there. Of course this state of the bowel accounted for the continuance of the symptoms of strangulation after the operation. Such kind of cases serve as a warning of the danger of delaying to operate after a fair trial of the taxis. He need scarcely allude to general peritonitis as a cause of death in strangulated hernia.

Mr. HEWITT said with regard to one point, that of the hernia being up in the inguinal canal, and looking like an inguinal hernia, Mr. Croly would recollect another case of a similar kind, also occurring in a female. The hernia had remained for three weeks or a month in the inguinal canal without showing many symptoms; and in that case, Mr. Croly expressed his opinion, that although it was apparently an inguinal hernia, it was really a femoral one, and in that case the hernia was returned without the opening of the sac. In the present case, however, although Ginbernat's and Poupart's ligaments had been both cut across, the intestine would not return, owing to the bands of lymph which had been formed. He had seen Mr. Croly operate, and fail to return the sac, and in one case he found complete constriction in the neck of the sac. He should therefore say, that the sac should be opened as a general rule.

Dr. JAMESON had operated in a great number of cases of hernia, both inguinal and scrotal, in Mercer's Hospital, and had been probably as successful as any other surgeon there; for out of 19 cases, he had lost only three. In one of the latter cases, there was a tumour in the groin, in the locality of the femoral ring. On consultation with his colleagues, it was decided that he should cut down on this. Accordingly he cut down in the usual way, and came upon a gland in the groin, about the size of a walnut. He cut down upon it and into it, fully to the depth of the blade of the knife; and he also dissected round it. However, it was decided that they should close the parts and leave the patient alone. Symptoms of strangulation continued, and she died in 36 hours afterwards. On a post-mortem examination they found, when they cut into the gland in the groin, that there was in the *centre* of it a small knuckle of intestine, not larger than a hazle-nut. This case was a warning to surgeons when they found a gland in the groin, to proceed with great caution. He invariably opened the sac, except in one instance, and that was a case of very recent femoral hernia in a female—in fact the hernia was not down 24 hours until he operated. He owed all his success to operating early. The taxis having failed, he never waited. He looked upon that as the reason that all his cases were so exceedingly fortunate. In one of the cases he lost, when he opened the sac, a flow of liquid fæces came out, and he thought the man would die on the table. He died in some five or six hours after the operation.

Mr. FLEMING observed that the diagnosis of strangulated femoral hernia was often very difficult, especially if there was a large deposit of fat. However, by proceeding cautiously the femora lcould be distinguished from the inguinal hernia. As to the shape of the sac, it varied very much, and the elongated sac was a form that very often existed in these cases. In diagnosing the contents of the sac, they were assisted by percussion. According as the sounds were dull or clear, they could determine the presence of the intestine, or of fluid, in the sac. As to strangulation, that was generally indicated by the obstinate constipation of the bowels; and in cases of femoral hernia, he would be disposed to act promptly.

Mr. STAPLETON said that in femoral hernia, although the ligamentous stricture was divided, still there might be stricture in the neck of the sac, and the way to prevent that was to get the assistant to take hold of the sac on each side, and if there was stricture in the neck, the surgeon could divide it.

Mr. CROLY, in reply to Mr. Hamilton, said that the bowels acted only through the artificial anus. In this case they found a large lymphatic gland, and removed it. Sir A. Cooper had called attention to this point, and warned the young surgeon to take care lest a knuckle of gut should be found behind the gland. He quite agreed with Dr. Jameson as to the importance of operating early. Mr. Hey, of Leeds, told him that he never lost a case of hernia, and that he operated the moment the patient came into hospital. Mr. Fleming appeared to think strangulated femoral hernia of the shape alluded to in this case, not an uncommon form, but he (Mr. Croly) thought it was very rare, and Dr. Hargrave, who had had great experience in cases of strangulated hernia, and had operated many times for it, was also of opinion that it was very rare.

FIRST STAGE IN THE FORMATION OF URINARY CALCULUS.

Mr. B. WILLS RICHARDSON said—We are indebted, sir, to the labours of Dr. Lionel Beale for some valuable facts concerning the origin of certain urinary calculi. "It is important," as he observes, "to bear in mind that there was a time when even the largest calculus was a microscopic object, when it might have been removed from the organism and the formation of 'stone' entirely prevented."

All surgeons familiar with Dr. Beale's labours cannot doubt that he has had most extensive experience in the analyses of urinary calculi, therefore, any statements of his regarding the formation of calculi, should have great weight. How, then, does he say the great majority of urinary calculi commence?

According to his observations, "the 'nucleus' of almost all calculi exhibits the same composition and characters, and is formed in the same manner. If small *uric acid* calculi be soaked in liquor potassæ, the uric acid will be dissolved and a 'nucleus' will be left which consists of a little mucus with small fragments of oxalate of lime, and in many cases *well-formed dumb-bell crystals* of oxalate of lime may be clearly demonstrated." Of course the same remark applies to ordinary mulberry calculi. Finally, Dr. Beale has come to the conclusion that *dumb-bell* and *spheroidal crystals* of *oxalate of lime* "are very frequently the 'nuclei' around which other insoluble or partially soluble materials are deposited."

That this opinion is well founded, is shown by the fact, that microscopic aggregations of *dumb-bell* crystals of oxalate of lime, are frequently seen in the uriniferous tubes of the kidney.

Having recently met with some oxalate of lime deposits in the urine of a patient under the care of Dr. Head, in the Adelaide Hospital, which, to a great extent, support the view of Dr. Beale, that the *dumb-bell* crystals frequently form the nuclei of calculi, I am induced to draw the attention of the society to the specimens. They are preserved in glycerine, and not only are there *dumb-bells* and *rosettes* of oxalate of lime, but there are also vast numbers of octahedra of the same salt, as well as crystals of lithic acid of various forms and sizes.

If the members examine the slides they cannot fail to see that there are several microscopic masses of *dumb-bell* crystals on each of them. Now, Dr. Beale's remarks—and I have frequently verified his observation—that the *dumb-bells* and their modifications have a great tendency to collect and adhere together. In fact you may move them about, shake them in water, and yet they will continue to adhere together. The crystals in the glycerine before the society were washed over and over again, shaken about in distilled water before final mounting, and yet they did not separate, or at least masses remained of sufficient size to form microscopic calculi. The *dumb-bells* became mutually dovetailed, as it were, and whatever spaces existed between them, finally became obliterated, as seen in many of the specimens under the microscope on the table. Dr. Beale gives, in his work on the urine, illustrations of two small calculi apparently formed in this manner. When such microscopic calculi are formed, they may become either the nuclei of the mulberry calculus; or should the urine be

charged with urates or phosphates, these salts may be deposited upon them; but in case of alternate variations in the characters of the urine, the alternating calculus may be the result.

The cells before the society, as already mentioned, contain not only octahedra; *dumb-bells*, and their modifications, but also a large quantity of uric acid crystals, so that we can readily conceive, how easily a compound stone could be formed in the person, in whose urine they were found.

Some of the gentlemen present may remember, that the late Dr. Golding Bird considered the *dumb-bell* crystals were probably composed of oxalurate of lime. This, however, is not now believed to be correct, for subsequent investigations to those of Dr. Bird have, I believe, proved that they also, are composed of oxalate of lime. The *dumb-bells* before the society, are not seen by ordinary light, for I thought, that on account of their property of polarising light, it would be better to exhibit them to the society with the assistance of the polariscope, which renders them easily seen, and at the same time, most beautiful microscopic objects.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 4, 1868.

ABYSSINIA.

THIS subject is beginning to be looked for regularly by the readers of all kinds of periodicals. Already a host of correspondents—special, general, and occasional—have done their best to gratify the public appetite for news from the little known land where our soldiers are encamped, and writers in magazines and reviews are doing their best to popularize such knowledge of Abyssinia as we possess. The *Argosy*, now under the editorial direction of Mrs. HENRY WOOD, lately had the fortune to issue a narrative by one of the captives. This is sure to be eagerly read, and will, no doubt, introduce this magazine to many new readers, who will also find in it a good supply of other pleasant reading.

At the meeting of the Royal Geographical Society last week, two very important communications were read from Mr. CLEMENT'S MARKHAM, who has been sent out by the Society. Mr. MARKHAM deals principally with the physical geography and the geology of the localities he has hitherto explored, although many other subjects are alluded to, and that in a manner likely to attract attention. His communications are very ably arranged, being divided into sections, each of which is devoted to a certain portion of the route, or to some particular locality. Of course, Annesley is the first part to claim attention, and Mr. MARKHAM confirms other observers in its deceptive appearance from the anchorage, where it looks green and pleasant, but, on landing, is found to be a sandy plain overlying clay. This plain is, however, intersected by dry beds of torrents, overgrown with such plants as salicornia, accacia, and calotropis; and there are also patches of coarse grass. Mr. MARKHAM found broken pieces of fluted columns, capitals, and fragments of a very dark-coloured volcanic stone on some of the mounds. On excavation, the bronze balance and chain of a pair of scales were brought to light, forming the first discovery in the ruins of a commercial city with which the Greeks, in the days of the Ptolemies, carried on trade. At a little distance from the mounds on the right bank of the Hadas, one of the streams which crosses the plain, is the modern village of Zoulla. The Shohoes inhabiting it are a black race, with rather woolly hair; they are further described as small-boned, but their features are said to be regular, and, in some instances, even handsome. They wear cotton cloth round the middle, and a cloak of the same material. Their head and feet are bare, and they are armed with a curved sword, a spear, a club, and a leather shield. They cultivate a little jowaree, and have cattle of a very diminutive breed, asses, horses, and sheep. Their huts are scattered over the plain. Their burial places are extensive, and appear to be used by the people for a considerable distance around them, there being only two between the coast and the entrance to the Senafé Pass. The graves are marked by oblong heaps of stone, with upright slabs at each end. A hole is dug about six feet in depth, and at the bottom a small cave is excavated for the reception of the body. The tomb is closed with stones, and the hole leading to it is filled up. The plain around Zoulla abounds in game—antelopes, gazelles, hares, bustards, and spur-fowl. During rains, the game is said to be still more plentiful. The coast rains usually commence in December, but there is no great fall.

A very interesting section is that devoted to the exploration of the county around Annesley bay, and the trip from Zoulla to Howakel bay. A running stream was found forty-nine miles from the sea, and fourteen from the mountains. Near a settlement in this district was a great salt plain, which may be looked upon as the remains of a vast lake outlet, the intense heat rapidly evaporating all the water. The stream, we have mentioned, is called the Ragolay, and it seems that the eastern drainage of the whole Abyssinian water-sheet from Senafé to Atebi (seventy geographical miles distant from each other), consists of its tributaries. In one part, the Ragolay was found to be perennial, but in its course towards the sea it dips into a depression 193 feet below the sea-level. This depression probably arises from past volcanic action.

The other sections of Mr. MARKHAM'S reports are equally interesting.

ABOLITION OF PLURALISM IN THE DUBLIN HOSPITALS.

As many of our readers are doubtless unacquainted with a recent reform movement in some of our Dublin medical institutions, amounting almost to a professional revolution, we propose to give them information respecting the transactions above referred to, and to give our opinion thereon. Some months ago the Superioress of the Convent of Mercy in Dublin, resolved to put an end to pluralism in hospital appointments, so far as her authority and influence extended. Accordingly, she intimated to a gentleman of eminence, who held the post of Clinical Surgeon in the Mater Misericordiæ Hospital, as well as in the Jervis-street Infirmary, her opinion that, for many reasons, it was desirable that he should make his choice between the hospitals in question. This he immediately did, resigning his post in the Jervis-street Infirmary, and so creating a

vacancy, which was filled by the appointment of Mr. MELDON.

Soon after, a vacancy occurred in the surgical staff of the Richmond Hospital, by the retirement of Mr. FLEMING, whose place the Governors filled by appointing thereto Mr. WILLIAM STOKES, Surgeon to the Meath Hospital, with the distinct proviso, on the motion of Sir D. CORRIGAN, that before the opening of next winter session, Mr. STOKES shall wholly resign his surgeoncy to the latter institution.

On the 1st of February the Board of Trinity College passed the following resolution :—

"That in future no University Professor in the School of Physic shall be allowed to hold an appointment as Medical Officer to any Clinical Hospital other than Sir Patrick Dun's Hospital. *This rule not to affect existing arrangements.*"

We understand that this resolution was passed with special reference to Dr. BENNETT, University Anatomist, who is Surgeon to Sir Patrick Dun's Hospital *ex officio*, under the provisions of the Amended School of Physic Act of 1867. That gentleman made a request that he should be allowed to compete for the vacancy in the Surgical Staff of the Meath Hospital ; but his request was not granted.

On the 21st of February, the President and Fellows of the King and Queen's College of Physicians passed a similar resolution to that just quoted with reference to the four Professors of the School of Physic appointed by them.

During the course of the debate on this question, we understand that weighty reasons were advanced by some of the Fellows in favour of the proposed resolution ; while it was alleged, on the other hand, that however excellent as an abstract principle the proposed change might be, yet that *at present* it would be found to operate prejudicially, by shutting out from competition for the professorships the class of men who are best fitted to fill the most important office of clinical teacher.

However, the reasons that a man cannot be in two places at one time, that he cannot teach two clinical classes properly, that sometimes circumstances will arise in which the pluralist can hardly act rightly with reference to one institution, except by preferring its interests to those of the other ; and that by the system of pluralism young men of promise and ability are debarred from rising in their profession, and throwing the energy and zeal of younger years into the cause of medical science : all these reasons prevailed, and the resolution was, as we are informed, passed unanimously. In estimating the full meaning of this resolution, the actual clinical state of Sir Patrick Dun's Hospital should be remembered. Of its three *ex-officio* physicians, Dr. BANKS is Physician to the House of Industry Hospitals, while neither Dr. LAW nor Dr. AQUILLA SMITH are attached to any other *clinical* hospital (*i.e.*, to a hospital where medicine and surgery is taught to students). Of its three *ex-officio* surgeons, Dr. R. W. SMITH is Surgeon to the Richmond Hospital, Dr. MCDOWELL is *Physician* to the House of Industry Hospitals ; while Dr. BENNETT is Surgeon to Sir Patrick Dun's, and to that only.

This system has not been found to work well at the last-mentioned institution. So badly has it operated indeed, and so sensible have the Board of Trinity College been of its defects, that they have ineffectually offered one of the surgeons above-mentioned, a man of encyclopædic learning in surgery, an additional endowment of £100 a-year, provided he would resign his other clinical post, and adhere to Sir Patrick Dun's only. But to return to our narrative :—

During the course of the debate at the College of Physicians on the 21st ult., and before any resolution had been arrived at, Professor BANKS tendered his resignation of the King's Professorship of Physic, which he has most ably filled for eighteen years. He was understood to state his reason for doing so to be this : that he had intended resigning within a few months, but, that the force of the arguments to which he had listened was so great, and the expressions of opinion were so general, as to convince him that he had best do all he could to support the unmistakable opinion of his brethren by refusing to take advantage of the saving clause in favour of vested rights. Dr. BANKS's most honourable conduct in this matter cannot be sufficiently praised or held up as an example for others to follow. He was notably most regular and zealous in the discharge of his clinical duties at Sir Patrick Dun's Hospital. The College of Physicians, at its meeting held on the 28th ultimo, accepted his resignation with the understanding that he shall hold his office until the beginning of May, after which three months' notice of an election to the professorship will be given. The election will probably occur in August, and as the place is worth nearly £400 a-year, and will probably increase in value, of course there will be many candidates. The competition is open to all, but as the electors are the Fellows of the College of Physicians, it is most likely that they will, as heretofore, elect one of their own body. Indeed, to do otherwise would be to admit that the ancient and learned College of Physicians of Dublin valued the attainments of their members at a remarkably low rate.

The new professor ought to be a man of some standing and clinical experience; of proved ability as a speaker and writer; and possessed of that courteous and affable demeanour towards students, for which Dr. BANKS has always been highly esteemed by his pupils.

On the 29th ult., the Board of Trinity College appointed the eminent ex-President of the Royal College of Surgeons, Mr. BUTCHER, to a surgical post in Sir Patrick Dun's Hospital, with the full consent of the governors. Mr. BUTCHER will be a salaried officer of the Board of Trinity College, and will have certain surgical beds assigned to him; but will not (so far as we have heard) hold any official title, or interfere with or displace any of the existing surgeons. By clause 4 of the School of Physic Act of 1867, the Board of Trinity College can appoint a clinical surgeon to fill the place of one of the *ex-officio* surgeons who may neglect his duty, and the Fellows of the College of Physicians have a similar power as regards the Physicians. Mr. BUTCHER is not, however, appointed under this clause; and it is not easy to see what his status will be, considering the Act of 1867 and its stringent provisions. He will have to resign his place as Surgeon to Mercer's Hospital.

We have now fully described the recent reform movement as regards the Dublin Hospitals ; and it only remains for us to express our opinion thereon. We think the movement fair and just to the public, the sick, the hospitals, and to the profession. There is, however, one illiberal monopoly still retained in connection with Sir Patrick Dun's Hospital to which attention ought to be called. We refer to the compulsory attendance of students of the School of Physic at that institution for one year, and at a higher rate of fees than is charged at other equally good clinical hospitals in Dublin.

We know this to be felt by students as a great grievance, and it is the more indefensible because it is entirely contrary to the liberal spirit which has dictated all the recent reforms in the School of Physic. Formerly no Dublin lectures were recognised by the University of Dublin save its own; and, therefore, the monopoly complained of was quite in keeping with that system. Now, however, all recognised Dublin lectures are received by the University; and there ought to be a thorough going free trade in clinical lectures also. Let students go where they get, or think they get, the best value. When the teachers know this they will act accordingly.

This monopoly is not required by Act of Parliament, and it may be abolished to-morrow if the Board of Trinity College and the College of Physicians agree to do it. On the other hand, we must in fairness state that clause eleven of the School of Physic Act of 1800 is still in force. By it every student in Arts of Oxford, Cambridge, or Dublin, of two years' standing and upwards, must pay three guineas to Dun's Hospital for one year's clinical attendance, and non-students in Arts *twenty guineas*; both of these sums are *in addition* to the nine guineas which students of either class must pay to the clinical lecturers for the same time.

If this clause be rigidly enforced, Sir Patrick Dun's Hospital must, before long, be closed to all but students of the three older Universities—that is, to the few; and it is surprising that it was not repealed in 1867, along with other clauses which prescribed regulations respecting lectures and lecturers, not a whit more unsuitable to the year of grace 1868 than this clause is.

It is saidt hat the College of Physicians are contemplating the institution of a new order of "Members," a middle class between the Fellows and Licentiates. If this be carried into effect, it will require some legislative enactment to allow the new order to be registered. In whatever Act a clause of this kind shall be introduced, a clause repealing section eleven of the Act of 1800 might also be inserted with advantage to the Dublin School of Medicine. "The School of Physic in Ireland" has no reason to fear competition, and ought to get rid of illiberal monopoly.

Notes on Current Topics.

The Public Health.

The returns of the Registrar-General for the week ending on Saturday, Feb. 22nd, were the following,—In London and 13 other large towns in the United Kingdom, 4655 births, and 2955 deaths were registered. The annual rate of mortality was 24 per 1000 persons living.

"The annual rate of mortality that week was 22 per 1000 in London, 25 in Edinburgh, and 33 in Dublin; 24 in Bristol, 21 in Birmingham, 23 in Liverpool, 28 in Manchester, 26 in Salford, 21 in Sheffield, 23 in Leeds, 23 in Hull, 20 in Newcastle-upon-Tyne, and 28 in Glasgow."

There were registered in London the births of 2315 children, of which 1159 were boys, and 1156 girls. The average number corrected for increase of population is 2251, in the corresponding weeks of the ten preceding years. The deaths registered were 1336, being 243 less than the estimated number for that week, in the ten previous years.

From zymotic diseases the deaths were 261, from small-pox 26, from measles 28, from scarlatina 30, from diphtheria 11, from whooping-cough 50, from fever 48, and 9 from diarrhœa. One hundred and forty-one deaths occurred from phthisis, 143 from bronchitis, 73 from pneumonia and 52 from diseases of the heart.

Several deaths occurred from accidents, and one female died of "paralysis," accelerated by fright from the explosion at the House of Detention, in Clerkenwell. Another is registered as dying in St. Joseph's Home, Notting-Hill, at the advanced age of 102 years.

Fever.

In the official records of the health of London, there are peculiarities which show the conditions of typhus as it makes its appearance in the several metropolitan districts. Thus, it was most prevalent for the last five weeks, and the mortality it occasioned was the greatest, in the poorest and most densely crowded localities. At the east end the average number of deaths from this disease was 9·4 to 10,000 of the population, per annum; in the central portion or the city proper, it was 9, while in the south, west, and north, it was only 6·8, 4·6, and 4·2, respectively.

"Since the commencement of the present year the deaths in London have averaged 39 per week, which is 13 below the average number of the corresponding period of the last 10 years, so that there is some indication of an abatement of this dreadful disease, which has of late years so ravaged the metropolis, particularly the east of London, where it has shown itself to be a disease of pauperism. Turning to the returns for the entire country, it is seen that fever always prevails epidemically in England and Wales. The large number of 177,288 lives were cut off by these forms of fever—typhus, typhia, and typhinia—in the 10 years, 1856-'65, averaging 17,729 deaths per annum. If the mortality of cases of fever in the country at large is truly represented by that of the London Fever Hospital, then it may be inferred that as 17,000 persons died in the different fever fields of England every year, at least 150,000 persons were attacked by these fevers annually."

According to Dr. Murchison, three varieties of fever which used to be returned under the general head of typhus, may be distinguished, and traced more or less distinctly up to their several causes. The first of these is typhus with blood spots on the skin, which is exceedingly fatal. This type is usually found where the population is excessive, or at least crowded, and it seldom attacks the patient twice. The second form is typhinia or continued fever, described as relapsing or famine fever. It may usually be traced to a specific zymotic matter, which is generated wherever human beings are collected together in a dirty condition, with inferior and insufficient food, and an inadequate supply of fresh air. The third variety is typhoid fever, or typhia, which is marked by an eruption of rose spots on the skin. So frequently this form takes its origin from the effluvia of night soil, that Dr. Murchison has called it pythogenic fever. Fæcal fermentation may also produce it spontaneously, or it may be communicated by the sick to the healthy, or by smells from the air of cesspools and drains. Next to consumption, typhia is most fatal to persons in the prime of life.

University of Oxford.

To-morrow, the 5th instant, Dr. Rolleston, Linacre Professor of Anatomy and Physiology, will resume the course of lectures which he commenced this term.

University of Cambridge.

On the 31st an examination for four minor scholarships will be commenced in Downing College. For one of these the natural sciences, in connection with medicine, will be required—chemistry, comparative anatomy, and physiology. Persons who have not entered at any college are eligible, but the emolument, £40 per annum for two years, will not be given until the minor scholar has entered at Downing College. Further information may be had of the tutors.

The Queen's Book.

A copy of this work has been presented by Her Majesty to most of the hospitals of London. Each copy bears the Royal autograph.

Coroner for West Middlesex.

This matter seems still undecided for, as we stated last week legal proceedings have been commenced. Several meetings have also been held by Dr. Hardwicke's friends, and it has been resolved to raise a public subscription to defray the expenses of an appeal to the law court, and probably, also, of the late election expenses. To us the whole affair forcibly illustrates the folly of leaving the election to a judicial office in the hands of the freeholders of the district.

Poor-law Medical Adviser for London.

The position to which Dr. Edward Smith has been lately appointed in connection with the provincial administration of the Poor-law will be occupied, as regards the Metropolitan District, by Dr. Markham, who has been appointed to that duty by the Poor-law Board. We consider it a matter for congratulation to the profession when a gentleman who enjoys so entirely the public confidence is selected for such a position, and we recognise in the choice of such men as Dr. Markham and Dr. Smith a determination to entrust important public duties to the best men who can be procured—a policy which, if persisted in by those in authority, cannot fail to be attended with the best results on the efficiency of the public service.

Poisoning—Wholesale, Retail, and for Exportation.

Under this title there is a lively article in the first number of the *Serio-Comic Magazine* devoted to the abominable adulterations of food practised so constantly by various dealers. Light and amusing essays of this kind are, perhaps, more read than systematic exposures of these frauds, and their writers are, therefore, entitled to the thanks of the community for popularizing facts which are too apt to be forgotten after scientific men have had their say. We welcome the new serial as we thus announce the article in question as the one most within our sphere. The public cannot too constantly be reminded of the dangers that arise from the rapacity of unprincipled traders.

Medical Patents.

Our attention has been recently directed to a passage in an old number of the *British Quarterly Review*, concerning Wollaston and his application of his scientific knowledge to the acquisition of wealth. As the reviewer's remarks have a direct bearing on the subject of medical patents, recently discussed in this journal, we lay them before our readers.

"Wollaston was fond of amassing money. There have not, indeed, been wanting accusations to the effect that if he had sought less after wealth, he would have done more for science. How far these charges are true we have no means of judging, as it does not appear from the published accounts in what exact way he made his money. That it was chiefly by the platina process is certain, but whether he engaged in the manufacture himself or only superintended it, we do not know. On this point we would only remark, that there is something, to say the least of it, very partial and unfair in the way in which obloquy is cast upon men of science, if they appropriate to themselves some of the wealth which their discoveries procure for others. If a successful naval or military hero is lavishly pensioned out of the public purse no one complains. It is not thought strange that a great painter or sculptor, while he justly declares his productions are worth untold gold, should, nevertheless, demand a modicum of coin from his admirers. Neither is the poet or musician blamed who sells his works to the highest bidder. But if a chemist, for whom there are few pensions and no peerages, thinks to help out a scanty or insufficient income, by manufacturing gunpowder, like Davy, or magnesia, like Henry, or malleable platina, like Wollaston, or guano, like Liebig, the detractors assail him at once. He has lowered the dignity of his science, and, it would seem, should starve rather than degrade his vocation. That vocation, so far at least as the practical fruits of his own labours are concerned, is to be a kind of jackal to start game which others are to follow—a beagle to hunt down prey which others may devour. Surely there is but scanty justice here, and some forgetfulness of a sacred text:—'Thou shalt not muzzle the mouth of the ox that treadeth out the corn, &c.'" —*From the "British Quarterly Review," number* vii. *(August,* 1846*), Article* 3, *p.* 104.

Good Wine in Bad Bottles.

Enough has been said and written of late on the question of wine, to make us suspicious of every bottle which is brought to table. No one can tell, even though the price he pays ought to be sufficient to indemnify him, still no one can tell, as he drains the bright glass which he has raised to his lips, that he is drinking the pure juice of the grape. So cleverly has the rich and delicate beverage been simulated, that none but a real connoiseur can detect the imposture; and the ordinary consumer must trust altogether to the honesty of his merchant for the purity of his wine. All this we have been lately led to believe and expect, but there is one fact in connection with the wine trade which we candidly confess we have never even dreamed of. We learn from a French journal that wine in bottle is frequently spoilt from the bad quality of the glass of which the bottles are made. Glass, as every one knows, is produced by proportionate quantities of white sand, and the alcalis, soda, and potass completely fused together. This requires a considerable heat, and the expense of the glass is raised by the cost of the fire which is necessary in its manufacture. This can be lessened by increasing the proportion of the alcalis, by which the melting process is more easily accomplished, and less firing required. But glass thus made is more or less soluble, particularly by tartaric acid, which is one of the elements of wine. A merchant found that the glass of a large number of the bottles, containing wine of a superior quality, had become opaque, and he commenced an action against the person of whom he had purchased the bottles. The court ordered an enquiry: an able chemist was employed, and discovered that the wine had been neutralized by the alcali in the glass.

We give our readers the benefit of the information we

have received. Everybody has read of new wine, in times gone by, being put into old bottles, and the bottles bursting, consequently the wine being lost. By more recent invention we obtain a bottle which can stand the test of age, and may be used over and over again, but, unfortunately it has at length been found that our wine is none the safer for all that. For though we are not astonished to find it sometimes unexpectedly covering our cellar floors, and the glass of the bottles lying in fragments around; yet, when we are thinking to regale our friends, and treat them with a splendid aroma, such as is rarely to be met with anywhere, we may have to sustain the mortification of presenting them with a glass of something which can scarcely be recognized as wine, and is not worth the price of the bad bottle in which it has been kept.

Hospital Changes in Dublin.

THE vacancy in the Medical Staff of the Meath Hospital, of which we informed our readers some weeks since, as having been caused by the transference of Mr. Stokes to the Richmond Hospital, remains yet unoccupied, and the pretensions of many candidates are canvassed, the religious element which rules so many appointments in Ireland entering to some extent into the conjectures. We believe that Mr. Stokes will discharge his duty as surgeon for the ensuing month, and that at the termination of that period the appointment will be made. The following is the clause of the Act of Parliament under which the selection will be made :—

"It may be lawful for said physicians and chirurgeons, or a majority of them, to elect a physician or chirurgeon in the room of any physician or chirurgeon, who from time to time by death, removal, or otherwise shall make a vacancy in said hospital, in consideration of their having served said hospital *gratis* these seventeen years past, and their having had a principal share in the support thereof during that period, and in erecting said building, as well as the relinquishing in behalf of themselves and their successors in said hospital all claim or title to the annual salary of one hundred pounds, which they otherwise would be intitled to in consequence of said act; any thing heretofore or in said act mentioned to the contrary notwithstanding."

The succession to the King's Professorship of Medicine, vacant by the resignation of Dr. Banks, will probably lie between Dr. Gordon, Dr. W. Moore, Dr. H. Kennedy, and Dr. Freke. Should the office be sought by Dr. Gordon, we believe his claims would be very favourably regarded, but if he should be elected he would become *de facto* physician to Sir Patrick Dun's Hospital, and must thereupon resign his present connection with the Richmond Hospital, which restriction may render his candidature doubtful. The claims of Drs. Moore and Kennedy are also very favourably spoken of, and there are other candidates whose pretensions do not entitle them to appear in the list of claimants.

A further change in the distribution of hospital appointments in Dublin has been caused by the appointment of Mr. Butcher to Sir Patrick Dun's, and his consequent retirement from Mercer's Hospital.

We learn that Mr. Butcher will join Sir Patrick Dun's as an extra surgeon, and not as one of the regular staff.

The British Lying-in Hospital.

WE understand that on yesterday (Tuesday) evening Dr. Eastlake brought under the notice of the Metropolitan Branch of the British Medical Association, the complaint of the treatment which he has received from the Governors of the British Lying-in Hospital. The late hour at which the proceedings terminated, make it impossible for us to report them in this issue of our journal. We have received a note from Dr. Edmunds in reference to our comments on his letter, published in our last. We regret that we are unable to insert it in the present issue.

THE President, Mr. Hilton, and the Vice-Presidents, Messrs. Quain and Cock, of the Royal College of Surgeons of England, together with Mr. Charles Hawkins, Mr Hancock, Mr. Buck, and Mr. Spencer Smith, have been appointed a committee to take into consideration the financial condition of the college, which is found to be most unsatisfactory. The expenditure in examinations—including remuneration to the examiners—on the museums and on the library are great and increasing, while the diminished number of candidates for the diplomas of the college renders its income smaller.

DR. OCTAVIUS STURGES, whose contribution to St. George's Hospital Reports we last week reviewed, has been elected Assistant-Physician to the Westminster Hospital. Dr. Sturges already held the post of Physician to the North London Consumption Hospital.

DR. F. SIMMS has been appointed Physician to the West London Hospital. Dr. Simms is the author of a little work entitled "A Winter in Paris."

VACCINATION REGULATIONS OF THE PRIVY COUNCIL.

AT the Council Chamber, Whitehall, this 18th day of February, 1868, by the Lords of her Majesty's Most Honourable Privy Council. Present—Lord President, Lord Robert Montague, Mr. Cave.

To the Guardians of the Poor of all Unions and Parishes, to all Public Vaccinators, and to all others whom it may concern.

The Lords and others of her Majesty's Most Honourable Privy Council (of whom the Vice-President of the Committee of the said Privy Council on Education is one) acting under the authority of the Vaccination Act of 1867, and all other authorities in this behalf, do hereby make and issue the following regulations, in addition to those already in force, for securing the efficient performance of public vaccination, and in respect of the revaccination of persons who apply to be revaccinated, that is to say:

I. *Places and Times for Vaccination under Contract.*

1. Except where the Privy Council, for reasons brought to its notice, sees fit in regard of any particular district to sanction a system of domiciliary vaccination, every vaccination district shall have in it at least one public station appointed for the performance of the vaccinations under contract; and where any such station has been provided for a district, no person resident within two miles thereof, and not being an inmate of the workhouse, shall be vaccinated under contract elsewhere than at such station, unless the vaccinator in the particular case be of opinion (which, if so, he is hereby required to note in his registrar), that for some special reason, the person whom he proposes to vaccinate cannot properly be vaccinated at the station.

2. Except under special authorisation from the Privy Council as aforesaid, or in so far as may be expedient at times when there is immediate danger of small-pox, vaccination under contract shall not be appointed to be performed at any station oftener than once a week.

3. And in any future contract concerning a vaccination district which is partly or wholly within a town, there shall not, except under special authorisation as aforesaid, be appointed within the town more than a single station, for the performance of the vaccinations of the district.

II. *Vaccination Districts in Towns.*

No part of the metropolis, or of any city, or municipal

borough, or town corporate, or other town, shall, in respect of any future contract, form by itself, or with any rural place, a separate district for vaccination, except with the approval of the Privy Council, unless it contain an estimated population of at least 25,000 persons, or else be as much of the metropolis, city, borough, or town as is for purposes of vaccination under the control of one board of guardians.

III. *Office of Public Vaccinator.*

After the expiration of the month of June next, no two or more persons shall be allowed to act severally as vaccinators under contract in anyone and the same part or district of any union or parish.

IV. *Revaccination.*

The performance of revaccination by the public vaccinator on persons applying to him for that purpose shall be limited in each case by the following conditions:—(1) that, so far as the public vaccinator can ascertain, the applicant has attained the age of fifteen years, or, if during any immediate danger of small-pox, the age of twelve years, and has not before been successfully revaccinated; and (2) that, in the public vaccinator's judgment, the proposed revaccination is not for any sufficient medical reason undesirable; and (3) that the public vaccinator can afford vaccine lymph for the purpose without in any degree postponing the claims which are made on him for the performance of primary vaccination in his district.

(Signed) ARTHUR HELPS.

Correspondence.

LEAVE OF ABSENCE FOR INDIAN MEDICAL OFFICERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I forward to you an Indian paper; the extract which I have marked from the *Delhi Gazette* I trust you will deem worthy of comment in THE MEDICAL PRESS AND CIRCULAR. Nothing can be more unjust than to exclude medical officers from the benefits of the proposed "Furlough Rules," for of all classes, in H.M.'s Indian Forces," none are more exposed to the baneful effects of climates, as the hottest winds, or heaviest rain can plead no apology for their non-performance of duty.—Faithfully yours,

G. MORROGH, M.D.,
Retired List, H.M. Indian Forces.

"The *Delhi Gazette* complains that, while the subject of 'Furlough Rules' is engaging the attention of the Secretary of State for India, and much thought by the Indian press is devoted to the necessity of the amelioration of those rules, we find the Government of India running directly counter to the effort by refusing to grant to regimental surgeons the same privileges, miserable and derogatory as they are, as are granted to regimental officers, who are able, on sick certificates to proceed to England for twenty months without losing their regimental position. We know well enough that it is contrary to the old order of things for medical officers to visit England on any leave whatever without losing their charge, whether civil or military. But the old order of things has in a great measure been swept away, and we wonder greatly that the Governor-General in Council should withhold, in spite of the solicitation of his Excellency the Commander-in-Chief, the very same concession which the State accords to other regimental officers. Why veto so trivial a boon? Why draw a marked difference between the surgeon and the other officers? But so it is, and so to the end of the chapter it will be. Other officers may go to England on sick certificate, and indeed enough go for twenty months, and return to their home in India—their regiment; but Sir John Lawrence rules that *regimental medical officers proceeding to England for twenty months on sick leave are not to return to their charges.* We confess we think this rather a hard, unnecessary, ungraceful blow. And it is a blow which by many will be keenly felt. For even if the boon sought under the auspices of Sir William Mansfield had been granted, it would have been after all but a miserably trivial concession, as the concession would in no way have involved the Indian Government in any monetary loss or monetary consideration."

[THERE is, we believe, no more frequent cause of jealousy and want of cordial feeling between combatant and Medical Officers than the invidious distinctions habitually and more unwisely introduced between them, by the authorities in the matters of discipline and privilege. Medical officers would be less than human if they did not feel that such differences are the result of an inbred hostility to the medical service, on the part of those who frame the rules, and who have been prejudiced against the noncombatant services by a similar policy; while it would be unreasonable to imagine that combatant will not take the cue from their superiors in looking down on their medical brethren.

Such a regulation as the foregoing hardly admits of any other explanation than a determination in the Governmental authorities to thwart the comfort and interest of their Medical Officers on all occasions. It is not the first time that such an unfortunate leaning has been evinced, and, in giving effect to such a prejudice, the authorities ought to be aware that they run counter to the feeling of the public, which has found, and will still find, vigorous and damaging expression through the public press.—ED. M. P. & C.]

Parliamentary Intelligence.

HABEAS CORPUS SUSPENSION (IRELAND) ACT CONTINUANCE BILL.

ON the order of the day for going into committee on this bill,

Mr. MAGUIRE said it was of the utmost importance to know something of the management of the Mountjoy Prison, where most of those taken up during the suspension of the Habeas Corpus Act were confined. An admirable physician, Dr. M'Donnell, who made certain important recommendations respecting the dietary and treatment of the prisoners, had, from one cause or another, ceased to be in the public service. His successor was Dr. Young. In the *Freeman's Journal* there was a report of an inquest held on Friday, 21st ult., on the body of a prisoner, Matthew Lynch. Up to the last moment the unworthy successor to Dr. M'Donnell appeared to have known nothing of the disease from which Lynch was suffering, which was pulmonary consumption; and the jury returned a verdict that the poor man should have been sent earlier to the hospital and that the doctor should be more attentive to external patients, meaning the unfortunate wretches confined in the miserable cells which were spoken of at the inquest. By what juggling did it happen that a humane man had been dismissed, and a man publicly branded by the verdict of a coroner's jury had been substituted in his place?

Lord MAYO—And now with regard to Dr. M'Donnell, who is a man of very high professional attainments, and for whom I have the most profound respect. Dr. M'Donnell on one or two occasions differed from the Directors of Convict Prisons, but they were not differences of a serious kind, and were generally settled by amicable discussion. But the fact is that the arrangements with respect to Dr. M'Donnell's services were such as did not exist in any other convict prison in the whole of her Majesty's dominions, and I say that the Medical Officer of Mountjoy male prison, having a large private practice to attend to, could not give that attention to the requirements of the prison which was wanted, and consequently the arrangement was exceedingly unsatisfactory. Now, I believe that an abler man than Dr. M'Donnell never discharged the duties of physician to a convict prison; but, looking to the nature of the duties which the doctor in such an establishment has to perform, it was impossible that they could be attended to by a man in private practice. What happened? Dr. Banon, the physician of the female convict prison, died, and an opportunity offered for consolidating the duties of the male and female establishments, and obtaining one medical officer for both. Representations were made to me by the Directors of Convict Prisons that it would be for the interest of the public service that the two offices should be held by one man. It was a considerable time before I acceded to that representation. I made inquiries as to what was done in England. I consulted Colonel Henderson and other gentlemen of great authority in such matters, and they all agreed that a worse arrangement than that of having a gentleman in private practice medical officer to a convict prison could not be; that the thing had been tried before; and that in every convict establishment of sufficient size, a medical man who had given up all his time to his duties in the prison was employed. Having this information at my disposal, and having to choose a successor to Dr. Banon, I told Dr. M'Donnell frankly what my opinions were. He did not altogether agree with me, but he

told me that his own practice was increasing so rapidly that it was very likely at a very early period he would find it necessary to retire from attendance at Mountjoy. That being the case, I had nothing to do but to take the advice given by such high authorities in the convict service, and appoint a resident medical officer for the male and female prisons at Mountjoy. Now, that is the whole story, and a more unfounded calumny was never propagated—and it was made the most of by the Fenian papers—than that Dr. M'Donnell was dismissed, and another gentleman appointed in his place, because he refused to sanction the very arbitrary and severe treatment of the prisoners confined under the Habeas Corpus Suspension Act. I know the hon. gentleman did not make such a statement in this house. [Mr. Maguire—"I did not say so."] I know you did not say so, but pages upon pages about it have been written in Ireland, and I believe that many have been led to accept it as a fact. Dr. Young, who has been appointed as medical officer to both the male and female prisons of Mountjoy, is a gentleman with whom I happen to be personally acquainted, and a more humane, an abler man, or one more competent to discharge his duties does not exist in any convict prison in the kingdom. And as long as Dr. Young remains in Mountjoy I am quite sure that neither the hon. gentleman nor anyone else will be able to prove harshness on his part to any particular prisoner. Mention was made to me in a communication from Dublin about the case to which the hon. gentleman has called attention, and I wrote for full and accurate information on the subject. I shall only say that in this matter, and in every other, I shall take care that every charge of this kind shall be thoroughly inquired into.

Mr. Bagwell expressed his opinion that it would be better to have a medical officer attached to Mountjoy who would not be entirely at the beck of the government. When he found that the jury had returned a verdict that the man into whose death they inquired, ought to have been sent earlier to hospital, and that the doctor should have been more attentive to exterior cases, he considered it a very grave matter. No doubt the verdict was a most unsatisfactory one for the medical officer, as it had been returned by a number of independent men upon their oaths, selected by the coroner from the general body of citizens.

The Speaker then left the chair, and clauses 1 and 2 were agreed to.

TROOPS IN THE MAURITIUS.

In the House of Commons, on Friday evening, in reply to a question,

Sir. J. Pakington said that the 86th Regiment had been sent from Gibraltar to the Mauritius last summer, but on arriving at the Cape was detained there in consequence of a serious epidemic then prevailing in the Mauritius. The military authorities here had sent orders to the General commanding at the Cape not to allow the regiment to proceed until he had received intelligence from the Mauritius that it might be done safely. Instructions had been also sent to the General in command at the Mauritius that he was to send to the Cape to have the regiment come off when he thought the epidemic had subsided. In the month of October, General Milman, who commanded in the Mauritius, thought that the fever had so far subsided that there was no danger, and he sent word to the Cape to that effect. As soon as transport could be obtained the 86th were sent on, and they arrived on the 27th of December. But in the meantime, the epidemic had broken out again, and assumed a very grave aspect in the town of St. Louis. Accordingly, when the regiment arrived, it became a matter for very serious consideration whether it could be safely allowed to land. A consultation was held between the General and the principal medical officer, and they decided that the regiment ought not to land. The surgeon of the regiment expressed in writing a very strong opinion that the regiment ought to go back to the Cape. That opinion was communicated to the colonel, but he remonstrated so strongly, solely on the grounds of discomfort and inconvenience in being sent back, that the General changed his mind and allowed the men to land. He took the precaution of sending the regiment as soon as possible to the out-stations, and dispersed the men in the more healthy parts of the island. The result was that up to the 17th of January, three weeks after the landing, only 25 cases of disease had occurred, and he was happy to add that no deaths had taken place. Still he thought it his duty to know why it was that the colonel of the regiment pressed that the regiment should be allowed to land, and why the General changed his mind and suffered the regiment to incur so great a risk. As far as he knew the facts he felt bound to say that the landing was not justified. He was happy to state that with regard to the Artillery and the Engineers the case was not so serious as the hon. gentleman seemed to suppose. He found, speaking of what had occurred in the Mauritius, that up to the 17th of last month, only 10 deaths had taken place in the Royal Engineers and only two in the Royal Artillery. In the 13th Regiment, which had returned last July, no great loss of life had occurred.

Medical News.

Her Majesty the Queen has been graciously pleased to present to the Hospital for Women, Soho-square, through Sir William Jenner, one of the Vice-Presidents, a copy of "Leaves from the Journal of our Life in the Highlands." The fly-leaf bears the following inscription and autograph:—"Presented to the Hospital for Women, by Victoria R." In accordance with her Majesty's wish, the volume has been placed in the library of the hospital for the use of the patients.

Army Medical Department.—25th February, 1868.—The Director-General presents his compliments to the Editor of The Medical Press and Circular, and begs to enclose for insertion a list of candidates of her Majesty's British Medical Service, who were successful at the competitive examination in August, 1867, and who have passed through a course at the Army Medical School, showing the combined results of the examinations, also a list of candidates who competed successfully for appointments as Assistant-Surgeons in her Majesty's British Medical Service at the examination held at Chelsea on 10th instant:—

ARMY MEDICAL DEPARTMENT.

List of candidates of her Majesty's British Service, who were successful at the competitive examination in August last, and who have passed through a course at the Army Medical School, showing the combined results of the examinations:

UNIVERSITY OF DUBLIN.—The Spring Commencements were held on Shrove Tuesday, February 25, when the following medical and surgical degrees were conferred :—

NOMINA CANDIDATORUM.

Baccalaurei in Medicinâ.—Thomas Whiteside Hime; Joseph Lawson; Arthurus Vernon Macan; Robertus M'Morran; Jacobus Franciscus Ryan; Alexandrus Haldane Stokes; Joseph Manly Tabuteau.

Magistri in Chirurgiâ.—Fredericus Ferdinandus Hill; Henricus Harris Langstaff; Arthurus Vernon Macan; Jacobus Franciscus Ryan; Alexandrus Haldane Stokes; Johannes Todhunter.

Doctores in Medicinâ.—Robertus M'Morran; Horatius Scott.

INSURING INFANTS' LIVES.—The disclosures which have from time to time been made respecting the suspicious deaths of infants whose lives have been insured, have elicited the following social science question in the columns of the *Public Health*, a paper devoted to social sanitary and medical legal matters :—"Considerating the high rate of mortality amongst infants which are entered upon the books of clubs, under the pretext of 'insuring their lives,' would it not be more accurate to describe the practice as 'insuring their deaths?'"

LIST of Entries in the Register of the Branch Medical Council (Ireland) for the month of February, 1868:—

Robert Locke Evans, 14, Kenilworth-square, Rathmines, county Dublin, Lic. 1867, and Lic. in Midwifery 1867, K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1867; Charles Boromes Jennings, Ennis, county Clare, Lic. R. Coll. Surg. Irel. 1867, Lic. K. Q. Coll. Phys. Irel. 1868; George Adams, 68, Grafton-street, Dublin, Lic. Apoth. Hall. Dubl. 1824; John Henry Penberty, Inverary Villa, Sydenham, Belfast, M.D. Qu. Univ. Irel. 1867, Lic. R. Coll. Surg. Edin. 1867; Matthew Henry Molloy, Dromore, county Tyrone, Memb. R. Coll. Surg. Engl. 1867, Lic. 1867, and Lic. Midwify. 1867, K. Q. Coll. Phys. Irel.; Michael Upington Greany, Mallow, county Cork, M.D. Qu. Univ. Irel. 1867, Lic. R. Coll. Surg. Edin. 1867; John Walton Browne, 14, Howard-street, Belfast, M.D. Qu. Univ. Irel. 1867, Memb. R. Coll. Surg. Engl. 1867, Lic. Midwify. R. Coll. Surg. Engl. 1867; William Belcher, Bandon, county Cork, Lic. R. Coll. Phys. Edin. 1867, Lic. Fac. Phys. Surg. Glasg. 1867, Lic. Apoth. Hall, Dubl. 1867; William Knox, Newtownstewart, county Tyrone, Lic. R. Coll. Phys. Edin. 1867, Lic. R. Coll. Surg. Edin. 1867; Benjamin Swift, Deputy Inspector-General of Hospitals, 61, Bushfield-avenue, county Dublin, Memb. R. Coll. Surg. Engl. 1839, M.D. Univ. Glasg. 1840; Joseph Henry Kenny, 21, James's-street, Dublin, Lic. R. Coll. Phys. Edin. 1867, Lic. R. Coll. Surg. Edin. 1867, Lic. Apoth. Hall, Dublin, 1867.

NOTICES TO CORRESPONDENTS.

Dr. Drysdale "On some points in Dr. R. MacDonnell's Lectures on Syphilis" received, and will appear as early as possible.

Several Hospital Reports, already in type, will appear immediately, including—The London, Guy's, St. Mary's, St. Bartholomew's, St. George's, &c., &c. Those gentlemen who have favoured us with the reports will, in each case, see proofs.

Several original communications are again unavoidably postponed, they will be inserted at an early date. Authors are requested to give us a little longer indulgence.

Communications received from—Rev. Dr. Kirwan, Honiton (enclosure); Weeden Cooke, Esq., (enclosure); Dr. Diplock, London; Ross Hastings, Esq., Shields; J. Lafarelle, Esq., Coleshill (enclosure); Dr. Cocker, Bank Hey; Dr. Goodwin Simms, London (enclosure); W. Rickman, Esq., London, (enclosure); W. THE CANTOR LECTURES AT THE SOCIETY OF ARTS.

Dr. LETHEBY'S SECOND LECTURE ON FOOD.

COMPARATIVE DIGESTIBILITY OF FOODS—FUNCTIONS OF DIFFERENT FOODS.

(Continued from page 199.)

As to the special functions of the several saline constituents of food, little can be said; but it is a remarkable fact that the *alkaline or basic phosphate of soda* is invariably found in the blood, while *acid phosphate of potash* is the chief constituent of the juice of flesh. Most likely the former is concerned in preserving the liquid colloidal condition of albumen and fibrin, and so keeping them from being lost by secretion, while the latter is engaged in an opposite duty. The alkalinity of the blood also helps in the oxydation of organic matters; and as the basic phosphate of soda is endowed, like an alkaline carbonate, with the power of absorbing carbonic acid, it is the chief agent whereby this compound is removed from the system. This is a remarkable property, and is one of the chief uses of basic phosphate of soda in the blood. In point of fact, when it is not there in sufficient quantity to perform this function it is replaced by an alkaline carbonate. We find this to be so in the blood of herbivorous animals, where the proportions of the two salts are the reverse of what they are in man, and carnivora. Some notion may be formed of the relative importance of the saline matters of the blood by reference to this diagram from Liebig.

PERCENTAGE COMPOSITION OF THE MINERAL MATTERS OF BLOOD.

	Man.	Pig.	Dog.	Fowl.	Sheep.	Ox.
Phosphoric Acid	31·79	36·50	36·82	47·26	14·80	14·04
Alkalies	65·66	49·80	55·24	48·41	55·79	60·00
Alkaline Earths	3·33	3·80	2·07	2·22	4·87	3·64
Mineral Acids and Oxide of Iron	9·22	9·90	5·87	2·11	24·54	22·32
	100·00	100·00	100·00	100·00	100·00	100·00

And in those cases where the phosphoric acid is deficient, it is replaced by carbonic acid. In man, for example, the quantity of combined carbonic acid in the ashes of the blood, is only 3·78 per cent., whereas in the calf it is 9·85, and in the sheep 19·47 per cent., so that in all cases the alkalinity of the blood remains the same.

The *salts of potash* in the juice of flesh have, no doubt, an equally important duty to perform, although of an opposite character; for while the alkaline phosphate of soda in the blood prevents the transudation of nutrient matter, the acid phosphate of potash in the muscular fluid promotes it; and thus it is concerned in nutrition and in the solution of worn-out tissues.

Earthy phosphates, especially *phosphate of lime*, are, perhaps, the agents for the consolidation of tissue; for not only are they present in the hard structures of the body, as the bones and teeth, but they also enter into the composition of flesh.

And not less important in the morphological functions of the animal body is the presence of *common salt*. It is a large constituent of every one of the secretions, and forms about half the total weight of the saline matters of the blood. Unlike the phosphates, however, it does not enter into the composition of tissue, but seems to be only a medium of absorption and secretion, and so necessary is it for this purpose, that it is not possible to alter, to any large extent, its proportion in the blood. If we drink water containing but little common salt in solution, it does not permanently dilute the blood, but passes off immediately by the kidneys; and if we try to increase the amount in the blood by drinking solutions of salt, as sea water, it refuses to be absorbed. This normal proportion of it in the blood is evidently a physiological necessity, which the conditions for diffusion imperatively demand. It is a curious fact, also, that common salt has the faculty of forming crystallizable compounds with most of the unorganised and effete constituents of the body. May it not, therefore, be an important agent of diffusion, and be thus concerned in the phenomena of absorption and secretion; for as colloidal matters—albumen and fibrin—cannot pass through the walls of the intestines, or the blood-vessels, it may well be that through the agency of common salt and the free acid of the gastric and muscular juices, they temporarily assume a crystalloidal condition, and are thus absorbed or secreted.

The constant presence of common salt in the secretions, and the necessity for it in due proportion in the blood, indicate the importance of a proper supply of it with the food. We perceive this in the instinct of animals, and in our own craving for it when it does not exist in sufficient

quantity in the food. Animals, in fact, will travel long distances, and brave the greatest dangers, to obtain it. Men will barter gold for it; indeed, among the Gallas, and on the coast of Sierra Leona, brothers will sell their sisters, husbands their wives, and parents their children, for salt. In the district of Accra, on the gold coast of Africa, a handful of salt is the most valuable thing upon earth after gold, and will purchase a slave or two. Mungo Park tells us that, with the Mandingoes and Bambaras, the use of salt is such a luxury, that to say of a man "he flavours his food with salt," is to imply that he is rich; and children will suck a piece of rock salt, as if it were sugar.

The experiments of Boussingault have shown that, although salt mixed with the fodder of animals, does not much affect the quantity of flesh, fat, or milk obtained from them, yet it seriously affects their appearance and general condition; for animals deprived of salt, other than that contained naturally in the food, soon get heavy and dull in their temperament, and have a rough and staring coat. Reulin states that animals which do not find it in their food or drink, become less prolific, and the breed rapidly diminishes in number. This is confirmed by Dr. Le Saine, who says, in his prize-essay on salt, that it increases the fertility of the male, and the fœcundity of the female, and it doubles the power of nourishing the fœtus. During the period of suckling, also, salt given to the mother renders the milk more abundant and more nutritious. It likewise accelerates growth, and gives a finer condition to the skin; and the flesh of animals fed with it is better flavoured, and more easily digested than that of animals which do not partake of it. In barbarous times the most horrible of punishments, entailing certain death, was the feeding of culprits on food without salt; and in the experiments of the French academicians, flesh deprived of its saline constituents by being washed with water, lost its nutritive power, and animals fed on it soon died of starvation. Even after a few days with such a diet, the instincts of the animals told them it was worthless as food; indeed, for all purposes of nutrition, it was, as Liebig says, no better than the eating of stones, and the utmost torments of hunger were hardly sufficient to induce them to continue the diet. There was plenty of nitrogenous matter in the food, but there was no medium for its solution and absorption, and hence it was useless.

The *oxides of iron*, and their homologues, the *oxides of manganese*, are largely concerned in the processes of sanguification and oxydation. They enter into the composition of the globules of the blood—manganese being the chief mineral constituent of the corpuscles of white-blooded animals, and iron of red. In fact the colouring matter of the blood discs (cruorin), as well as that of the muscles (myochrome), is a compound of iron and albumen (globulin), which has a remarkable property of absorbing oxygen when exposed to the air, and of giving it out again in the presence of reducing agents. In the one case it acquires an arterial tint, and in the other a venous; and the spectrum informs us that these two conditions of it are easily assumed—one by the presence of atmospheric oxygen, and the other by decaying organic matter. It is hardly to be doubted that these are the conditions of it in blood—the bright red oxydised cruorin being the form of it in arterial blood, and the dark reduced variety of it in venous. The functions, therefore, of both cruorin and myochrome are entirely of a respiratory nature; for, in the former case, it is the medium whereby oxygen is absorbed from the air in the lungs, and is carried with the blood discs throughout the body, and in the latter it may be the agent of intestinal oxydation.

Lastly, there is a mineral constituent of our food, *silica*, which enters into the composition of all the tegumentary appendages. Its presence is not of so much importance to us as to the lower animals, whose warmth is retained by a natural covering of hair or wool or feathers. In the case of birds, indeed, the quantity of silica in the feathers is very considerable, and Gorup-Besanez has described its physiological relations.

As to the proportions of mineral substances required in the food it is difficult to speak. Dr. Edward Smith says that an adult man requires daily from 32 to 79 grains of phosphoric acid; from 51 to 175 grains of chlorine (equal to from 85 to 291 grains of common salt); from 27 to 107 grains of potash; from 80 to 171 of soda; from 2·3 to 6·3 of lime; and from 2·5 to 3 of magnesia. According to Mr. Lawes, a very small portion of these salts is retained in the system; for in fattening pigs he found that of every 11 lbs. of mineral matter contained in the food only twelve ounces were stored up in the body, and this was chiefly the earthy phosphates, all the rest being either unabsorbed, or else used in the work of absorption, assimilation, and secretion. In most cases, therefore, there is sufficient saline matter, excepting common salt, in all ordinary food; but for all this, the presence of it in the water we drink is not an unimportant question. Four-fifths of the earth's surface are composed of calcareous strata, which yield water that is more or less rich in carbonate and sulphate of lime; and it may well be that this is a wise provision for the supply of these salts to the animal system. As Mr. Johnston has truly observed in his "Chemistry of Common Life," "The bright sparkling hard waters which gush out in frequent springs from our chalk and other lime-stone rocks, are relished to drink, not merely because they are grateful to the eye, but because there is something exhilarating in the excess of carbonic acid they contain and give off as they pass through the warm mouth and throat; and because the lime they hold in solution removes acid matters from the stomach, and thus acts as a grateful medicine to the system. To abandon the use of such a water, and to drink daily in its stead one entirely free from mineral matter, so far from improving the health, may injure it;" in fact, the water of a country may determine the diet of its inhabitants. The soft waters of the lakes of Scotland, for example, may have had something to do with the choice of brown meal; and but for the calcareous waters of Ireland the potatoe could not have become a national food.

And now, before I leave this part of the subject, it is right that I should say a few words respecting the functions of certain beverages (as tea, coffee, and fermented liquors) which have been more or less in use in all ages, as if from an untaught physiological instinct. Vegetable infusions, containing the same active principles—namely, astringent matter, volatile oil, and a crystallizable body rich in nitrogen have been resorted to for some undefined purpose by the natives of every climate; indeed, to use the words of Mr. Johnston, "the practice has prevailed equally in tropical and in arctic regions. In Central America, the Indian of native blood, and the Creole of mixed European race, indulge alike in their ancient chocolate. In Southern America the tea of Paraguay is an almost universal beverage. The native North American tribes have their Apallachian tea, their Oswega tea, their Labrador tea, and many others. From Florida to Georgia in the United States, and over all the West India Islands, the naturalised European races sip their favourite coffee; while, over the Northern States of the Union, and in the British provinces, the tea of China is in daily and constant use.

"All Europe, too, has chosen its prevailing beverage; Spain and Italy delight in chocolate; France, and Germany, and Sweden, and Turkey, in coffee; Russia, Holland, and England, in tea—whilst poor Ireland makes its warm drink of the husks of the cocoa, the refuse of the chocolate-mills of Italy and Spain.

"All Asia feels the same want, and in different ways has long gratified it. Coffee, indigenous in Arabia or the adjoining countries, has followed the banner of the Prophet, wherever in Asia or Africa his false faith has triumphed. Tea, a native of China, has spread spontaneously over the hill country of the Himalayas, the table lands of Tartary and Thibet, and the plains of Siberia; has climbed the Altais, overspread all Russia, and is equally despotic in Moscow as in St. Petersburg. In Sumatra, the coffee leaf yields the favourite tea of the dark-skinned population; while Central Africa boasts of the Abyssinian chaat

as the indigenous warm drink of its Ethiopian people. Everywhere, in fact, unintoxicating and non-narcotic beverages are in general use among tribes of every colour, beneath every sun, and in every condition of life. The custom, therefore, must meet some universal want of our nature, some physiological function which science has not yet explained; and, considering that these beverages contain essentially the same chemical compounds, it is remarkable that they should have been selected from the whole range of the vegetable kingdom." As Mr. Johnston truly observes, "What constitutional cravings common to us all have prompted to such singularly uniform results! Through how vast an amount of unrecorded individual experiences must these results have been arrived at!"

The principle constituents of these vegetable substances are:—

1st. A *volatile oil* on which their aroma depends, and which rarely amounts to one part in 150. 2nd. An *astringent acid*, of the nature of *tannic acid* in tea, and called *caffeic acid* in coffee, which give them their bitter styptic taste: it amounts to from 13 to 18 per cent. in tea, and to about 5 per cent. in coffee; and 3rd. A crystallized nitrogenous substance of an alkaline nature called *Theine* or *Caffeine*, and *Theobromine*. The average amounts of this alkaloid in different vegetable substances, according to Dr. Stenhouse, is here recorded:—

	Theine or Caffeine per cent.
Guarana or Brazilian cocoa from *Guarana officinalis*	5·07
Good black tea	2·13
Black tea from Kemaon, E. I.	1·97
Dried coffee leaves	1·26
Maté or Paraguay tea from *Ilex Paraguayensis* ...	1·20
Various samples of coffee-beans from 0·8 to ...	1·00

The physiological properties of this substance, and of its homologue, theobromine, are not clearly discoverable. Mulder states that they are not the agents concerned in the peculiar action of tea and coffee. Liebig, however, points to the fact that with the addition of oxygen and the elements of water, they can yield taurine, which is the nitrogenised constituent of bile, and he asks whether they may not be concerned in the production of that secretion. Theine, he also states, is related to kreatinine—that remarkable compound, produced in the vital process, and occurring in the muscular system of animals; and to glycocol, which we may suppose to exist in gelatine coupled with another compound. In fact, according to him, there are no drinks which in their complexity and in the nature of certain constituents, have more resemblance to soup than tea or coffee; and it is very probable, he says, that the use of them as a part of food depends on the exciting and vivifying action which they have in common with soup. Reasoning in this way it may be said that theine or caffeine, and theobromine are closely related in their composition to nervous tissue, and that therefore they are suited for the repair and renovation of the exhausted brain. Experiments made by Lehmann in 1854, with infusion of roasted coffee, and with caffeine, went to show that their chief influence on the human body was to retard the waste of tissues; that when, for example, an infusion of three-quarters of an ounce of roasted coffee was taken daily for a fortnight, the amount of urea and phosphoric acid excreted by the kidneys was less by one-third than when the same food was taken without the coffee. The empyreumatic oil was found to exert a stimulating action on the nervous system, and when taken in excess caused excitement and wakefulness. It also operated on the skin by producing a gentle perspiration, and it removed the sensation of hunger. The conclusion from these experiments was, that both tea and coffee exhilarate the nervous system, and by lessening waste enable the food to go further in its nutritive action; that with a given quantity of food, more work could be performed when these beverages were taken than otherwise; and that in old infirm persons, where the desire for tea is so strong, the waste and decay of the system was lessened. It operates, in fact, as a sort of lubricant of the animal system, and by oiling the machinery, enables it to work easier and longer.

The more recent experiments of Dr. Edward Smith are not exactly to the same purpose; for, in his opinion, tea promotes rather than checks the chemico-vital functions of the body, for directly after it is taken, the quantity of carbonic acid emitted from the lungs, and the quantity of air inspired are increased; and there is greater depth and freedom of respiration. In this way, he thinks, it promotes the transformation of starchy and fatty food; besides which, it increases the action of the skin, and by inducing perspiration, lessens the heat of the body. Coffee he says, has an opposite effect, for it lessens the action of the skin, and promotes that of the bowels; and its influence on the respiratory processes is somewhat less than that of tea.

It is manifest from all this, that we have yet to learn what are the special actions of these beverages; and why it is that they have been used in all times, and in all countries, as a means of supplying some natural want which science is unable to discover—that everywhere, the poor and the needy, the aged and the infirm, will make a sacrifice of even nutritious food for some such beverage as tea and coffee—that not less than 500 millions of the human race should make use of an infusion of tea; that more than a 100 millions should drink coffee; about 50 millions, cocoa; and not less than 10 millions of the inhabitants of Peru, Paraguay, and the Brazils, should use an infusion of maté, or guarana. In this country alone, there is over 100 millions of pounds of tea consumed annually, and, perhaps, about half as much of coffee. All this looks like the influence of some deep-seated necessity, which our philosophy is unable to fathom.

ON THE TREATMENT OF DISEASES OF THE SKIN.

By J. L. MILTON,

SURGEON TO ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

CHAPTER I.—PAPULÆ.

(Continued from page 112.)

C. Prurigo—Definition.—An eruption of small, pale papules, with a dry, greyish, or yellowish state of the skin, accompanied by intense itching, stinging and burning; wasting of the body; skin often marked by long abraded lines. Divisions: P. mitis (the lichen pruriginosus of Wilson), in which the papules are soft, smooth, solitary, and dispersed; generally scattered on front part of fore-arms, belly and thighs; often nearly of same colour as the skin; seen mostly in middle-aged persons, or the young. P. senilis or formicans, where the papules are fewer and larger, and accompanied with the most violent itching sensation of being stabbed with a needle, crawling and tingling; generally preceded or accompanied by considerable disturbance of the health, and a dirty-looking state of the skin, which is almost always marked by scratching.

In all forms of this justly-dreaded affection, the remedies which seem to have succeeded best resolve themselves pretty well into six classes.

1. *An alkali.*—Soda, for instance, seems to have always been a favourite ingredient in the prescriptions of the most successful practitioners. I do not attribute much importance to the form in which it is given; perhaps the carbonate, or a mixture of carbonate and sulphite, answers best. If there be much indigestion or acidity, ten grains may be given two or three times a-day, just after meals, either in an ounce of bitter infusion, with which a little compound tincture of cinnamon or spirit of nutmeg is combined, or it may be administered in conjunction with

aromatic confection and dilute hydrocyanic acid.[1] These remedies should be continued till indigestion is removed; should no indigestion be present they may be given up at the end of ten days or a fortnight.

2. A remedy is required which will act on the skin. Sulphur in some form or other is perhaps the mildest and most certain. Antimony, however, in such a preparation or dose as will not nauseate or depress, may also be prescribed with benefit, and I see no objection to combining these remedies with a little nitrate of potass. When the skin is very dry and harsh, as it almost always is, a powder containing these ingredients may be given on going to bed, in a little gruel or warm whey. Like the previously mentioned remedies, these need not be continued more than about a fortnight.

3. The use of either of these two sets of remedies should be accompanied by a course of medicine which will act gently on the liver and bowels, as, for instance, the occasional use of small doses of iodide of potassium, with rhubarb, either in the form of infusion or pill. A little mercury may be given in the shape of blue pill, combined with soap, henbane, and jalap or colocynth; or as grey powder, with nitrate of potass. Mr. Startin places mercury under interdict, though I have never seen it do the least harm.

4. But the great internal remedy in prurigo is arsenic, and in all very severe or long standing cases, and in those which do not seem to be benefited by the preceding treatment, I would advise that it should be immediately begun with; and the other remedies used only as auxiliaries, or in the place of the arsenic when it is necessary to interdict it. It may be prescribed in full doses, and when this is done, I am disposed to share Mr. Hunt's opinion that prurigo is not such an intractable disease if properly treated, although I am aware that the statement may be looked upon as a modern heresy, and that Mr. Wilson[2] considers it a stubborn and even a grave complaint in elderly persons. Under the old plan of treatment it seems to have resisted every attempt to subdue its malignity, and, perhaps, there were more suicides from prurigo than from all other diseases of the skin put together. Mr. Hunt says—"Of the entire recovery of a patient thus affected, or even of considerable alleviation of suffering, not one single gleam of hope can be gathered from any author who has written on the subject. And yet there is no truth in the whole circle of medical science more vividly impressed on my own mind, than that, under proper management, arsenic is an effectual remedy for this disease." Mr. Hunt bleeds to faintness in refractory cases before giving the arsenic; in one case he took about seventy ounces of blood from the arm, and probably fifteen additional ounces by leeches, and certainly, according to his statement, the success seems to have quite justified the means. Lisfranc used also to bleed in cases where the itching was connected with difficult menstruation, and the practice is said to have been very beneficial.

5. Certain remedies which seem to stimulate nutrition in some as yet unknown way. Of these two are well worth a trial—strychnia and cod-liver oil. The strychnia may be given in doses of a sixtieth or a sixty-fourth part of a grain every three or four hours till a decided effect is produced upon the disease, or till nervous symptoms show themselves, when it may be left off. It sometimes acts like a specific upon the pruritus, and when this symptom is once thoroughly quelled, we shall seldom, if ever, have much difficulty in dealing with the remaining symptoms. Nux Vomica was a favourite remedy with Neligan, but I believe we are indebted to Dr. Burgess for this mode of exhibiting its active principle. It should not be taken along with any other remedy, whereas the cod-liver oil may be given almost as an article of diet for a long time, and in moderate doses, quite irrespective of any other medicine the patient may be taking. I confess my entire ignorance as to how cod-liver oil and strychnia may act, and it may, perhaps, save some trouble if I say, once for all, that I am not prepared to offer any explanation of the action of medicines, for the simple reason that in respect to most of them nothing whatever is known for certain, and as to cloudy conjectures and cabalistic forms of speech, I leave them to those who like them. I am content to admire at a distance the person capable of solving such questions as causes and modes of action,[1] as I quite despair of my own ability to do so.

6. A free use of hot baths, especially the Turkish bath. I prefer the latter when it can be used, but when the patient is very nervous, suffering, or supposed to suffer, from disease of the heart, or subject to fainting; where he resides at a long distance from any establishment or baths of this kind, or where expense is an object, the hot bath is our only alternative, and fortunately it is a very good substitute. The water should be at quite ninety-eight or a hundred degrees of Fahrenheit. The patient, so soon as he enters the bath, should scrub himself all over with the flesh brush, lather the affected parts with either the soft soap of the London Pharmacopœia or Pears's transparent soap, and then let himself down into the hot water, in which he ought not to remain more than three or four minutes. Having dried himself thoroughly, he should apply any ointment he may be using and dress directly.

But the Turkish bath is the thing; it scarcely ever fails to do good, and is, perhaps, more peculiarly suited for prurigo than for any other disease of the skin. There are many persons in the habit of sponging all over daily, and who, therefore, have quite made up their minds that they require no other kind of purification. They cannot too soon be undeceived as to the efficacy of water used in this way; it will no more free the skin from soot, dust, dead scarf skin, and secretion, than rubbing a horse gently down with a soft towel will make his coat glossy. To rid the surface thoroughly of these impurities, two things are necessary: free perspiration must be induced, and the skin must be well rubbed and kneaded. Trainers are well aware of this, and when preparing a man for a fight, make him perspire freely, and then rub him down with a hard towel. The vigorous system of cleansing adopted in a Turkish bath is more like that used in training than any other, and will soon open the eyes of those who put their faith in cold sponging only, by bringing away an unexpected quantity of dirty skin. As there is no danger to be apprehended from the use of the bath, so long as the simple precaution is adopted of not staying in too long at first, and always taking the bath on an empty stomach, it can scarcely be overdone. I have known one taken three or four days together without any harm arising from it, and should not anticipate any.

Some most extraordinary objections have been made to it. Mr. Hunt, for instance, expatiates with grim sarcasm on the portentous aspect of things on entering a Turkish bath—the air so hot as to make one fancy that it cannot be breathed without setting the lungs on fire, the kneading and trampling on the patient, and the drowning with a deluge of cold water, but he admits that it cures fanciful people of their whims in superlative style. Then, one of the whims it will cure them of is fancying there can any harm come from using the bath.

Whichever form of bath be adopted, I would strongly insist upon the necessity for taking it regularly and often enough, and not yielding to any nonsense about baths being lowering, weakening, &c. I dwell upon the subject because the advantage of hot bathing in prurigo generally so soon becomes manifest. If nothing else be gained, free perspiration is promoted, and though this is no panacea, yet it is attended with relief. Prurigo often breaks out in persons who have nothing to reproach themselves with in regard to cleanliness. Mr. Startin, indeed, says,[2] "that the neuralgic itching which some writers consider as a form or variety of prurigo is, perhaps, more frequently met with in the respectable walks of life than any other cuta-

neous affection." Such persons often seem surprised at being told to make free use of hot baths, but they forget that they do not take sufficient exercise to keep the skin in a healthy state, and that means which would do very well with men riding twenty miles a-day, or working hard at training, are quite inefficient when exercise is reduced to a gentle stroll. Elderly persons in good circumstances, and people who have retired from business, often seem to think it is hardly respectable to go beyond a steady walk, but prurigo will not yield to such gentle means, and till regular active exercise has become a settled habit, the action of the skin must be encouraged. In all cases I think no woollen ought to be worn next the skin.

Mr. Wilson gives generous diet and tonics in this disease, and considers arsenic, properly given and watched, as a specific. Frictions, baths, carbolic acid soap, and juniper-tar soap, are his chief local remedies, but he looks upon the prognosis as doubtful, on account of the exhaustion and suffering which accompany the complaint.

Mr. Startin's treatment of prurigo is that of lichen; he relies chiefly on mineral acids, chalybeates, opium, and ammonia, and has never found benefit from mercury or arsenic; on the contrary, they rather do harm. In a very severe case of prurigo formicans, recorded by this gentleman, twenty drops of dilute sulphuric acid and ten of Batley's sedative three times a-day, followed by tincture of muriate of iron, in infusion of quassia, and an opiate at bedtime, proved perfectly successful. These means were, however, seconded by the use of an ointment of white precipitate of mercury and creosote, ten grains of the salt, and a few drops of the fluid to an ounce, and after this a weak solution of bichloride of mercury in creosote water, used warm; later on, the ointment was entirely discontinued, and bisulphuret of mercury was added to the lotion. A strict diet, consisting of milk, bread and boiled meat was observed. Mr. Startin finds hot air baths and cinnabar fumigations of great service. Dr. Neligan[1] used to prescribe iron in infusion of hops, with the juice of conium in pretty large doses. He found in the prurigo of old people great benefit from the use of this remedy along with magnesia. Some years ago, Dr. John Waterfield communicated to the *Lancet* and *Medical Gazette* a paper on the value of tar and charcoal pills, and he now tells me that he has treated several cases of prurigo very successfully with this remedy. Dr. Hillier[2] says that in some chronic cases diuretics, "such as the sweet spirits of nitre, decoction of broom, with the compound tincture of juniper and saltpetre," are of benefit. Dr. Purdon communicated to the *Journal of Cutaneous Medicine*[3] three cases in which the bromide of ammonium in doses of from ten to twenty grains effected a very rapid cure.

Hebra, who only admits prurigo mitis and formicans, views the malady in its gloomiest light; the picture is filled in with the most sombre tints that utter despair of being able to do any good can lend. The patient is doomed *tenero de ungue*. The relentless malady begins with childhood; even in his schoolboy days the martyr to it is an outcast; playfellows and masters alike shun and worry the victim of unappeasible itching. As he grows up, he is expelled from society or becomes a recluse; if he be a working man, he must not sleep in the same room with a fellow workman. He dare not try to establish a home, nor should, he already possess one, can he bring a wife to it. With advancing life the disease acquires more hold on the system, and only leaves him in the grave. Till that hour comes, he knows no hope and no peace. The complaint is not difficult to cure, for the simple reason, that it is incurable,[4] and all that the physician can do, is to make the patient's condition a little more tolerable. Hebra seems never to have given arsenic a fair trial, and it may be safely predicted that so long as he does not, he will find the complaint as refractory as he describes it to be. He utterly abjures bleeding, purgatives, and starvation, possibly with reason, but in point of fact I know nothing of the disease as spoken of by him, and never read of it in the pages of any other writer. Possibly in this severe, hopeless form it is as peculiar to Austria as pellagra to Italy.

In some cases, particularly when prurigo attacks the pudendum, scrotum, or anus, the itching is so intolerable that something must be done locally for it; indeed, the itching is the symbol of the malady, the one essential and tangible symptom, and the cure of it is the cure of the disease. Mr. Wilson recommends, in a general way, that the skin should be frequently rubbed with a damp sponge dipped in fine oatmeal; after this, the tincture of croton, made by steeping an ounce of bruised croton seeds for a week in four ounces of spirit, is applied, and after this has been done a few times, a lotion of bichloride of mercury in almond emulsion, fifteen or twenty grains to a pint, will often prove very efficacious. Painting the surface with iodine is useful, as is also glycerine applied with a sponge. For the affection of the pudendum, Bateman recommends a lotion made of two grains of bichloride (oxymuriate) of mercury in an ounce of lime-water. Mr. Wilson says the juniper-tar ointment is peculiarly valuable in this variety. In pruritus of these parts injections of very hot water, juniper-tar ointment, blisters to the thighs, and small bleedings, seem, from all accounts, to be the most reliable means of cure. Mr. Wilson has found an opium injection relieve the irritation after all other means had failed. Strong nitric oxide of mercury, ointment, and podophyllin in doses of one-sixth of a grain, are said to have proved of great service in prurigo of the anus. Mr. Startin, in a case related in his lectures, where the scrotum was also affected, directed mucilaginous hip-baths, daily ablutions with yolk of egg and tepid water, the application twice a day of very dilute mercurial ointment, with a few minims of creosote, strict diet, and one-sixth of a grain of bichloride of mercury in cold infusion of hops three times a-day. The case was very severe, and occurred in an old man; but a cure was effected in little more than two months. In the prurigo of old people generally, Mr. Startin's prescription for external use is a liniment of glycerine and trisnitrate of bismuth or powdered talc, rubbed in with a flesh-brush. Dr. Frazer recommends[1] for trial finely powdered camphor mixed with six or eight parts of rice or potato starch, and a small quantity of acetate or carbonate of lead. This is dusted on the skin three or four times a-day, its action being aided by calomel ointment. Latterly, Dr. Neligan confined himself almost entirely to chloroform ointment, which seems one of the best, if not the best, ever introduced. It is made by mixing half a drachm of chloroform with an ounce of cold cream. I believe this and the lotion given below[2] are two of our most valuable remedies.

Mr. Balmanno Squire considers[3] that prurigo senilis is always due to pediculi, and we may naturally expect to find that his principal reliance is upon external means. That in some persons pediculi will induce symptoms which might very easily be mistaken for prurigo is possible enough, but that they ever bring on genuine prurigo, a disease in its severer form so generally associated with some deep-seated constitutional disorder, is a very different matter. Mr. Naylor, who thinks[4] the insect cannot produce any form of this complaint, says he has known a very weak nitric acid lotion—half a drachm to eight ounces of water, or one of bismuth, a scruple to six ounces of water—prove exceedingly serviceable. He also says that when prurigo is an idiopathic affection the use of chloroform is often of great service, applied either in the form of vapour or of an ointment consisting of equal parts of chloroform and camphor liniment.

CASE OF EXTRA-UTERINE PREGNANCY.

By JOHN MOREWOOD, M.R.C.S.I.

I WAS engaged in the month of March, 1867, to attend Mrs. B., the mother of three or four children, who expected her confinement early in the month of June. She occasionally sent for me during the interim, owing to frequent attacks of uterine hæmorrhage, which were sometimes very profuse, but generally yielded to the application of a sponge moistened in vinegar and water, as a plug in the vagina.

The placental murmur could be clearly and distinctly heard, and the motions of the fœtus plainly felt so far on as nearly to the end of the ninth month, when one morning she was seized with very severe spasmodic pains in the left portion of the abdominal region. She immediately sent for me, and I endeavoured to relieve her by stuping, opiates, and emollient enemas; notwithstanding, the pains continued for two or three days, and no appearance of labour, and as I could not by the stethescope discover any fœtal murmur, I concluded the child was dead.

I had very great difficulty in allaying the fears and calming the distressing apprehensions of the woman, who felt the greatest uneasiness and alarm lest she should herself die.

I administered occasional anodynes, gave her light and nourishing diet, and kept her confined to bed, while another month passed away, and as yet no labour or appearance of it.

I was becoming rather uneasy myself as to the result of the case, when one day, almost six weeks after I had found that the child was dead, the woman sent for me, and on my going to her she told me, in a great fright, that she had had a slight diarrhœa, and when on the night-chair had passed, with great agony, something like the bones of a rabbit, but which, on my examination, turned out to be a portion of the side of the thorax of a fœtus, with the ribs, clavicle, and sternum attached.

I then immediately examined per anum, and found an opening through the rectum, behind the uterus, about three or four inches from the verge of the anus, into which, by inserting the tips of my first and middle fingers, I could plainly feel the outlines of a full-sized fœtus in a state of decomposition, and from which I was enabled to remove some more ribs, with a humerus, clavicle, and a portion of a forearm, and then I had to desist, as she was both exhausted and greatly alarmed.

I continued to visit her occasionally for a month, and each time I brought away a few bones, portions of the ribs, cranium, thigh, leg, &c., generally using a lavement of warm water, which brought off decomposed pieces, and afforded very great relief.

She was very thin and pale, and had a nasty diarrhœa during the latter part of her illness. I occasionally gave her castor oil, with anodynes at night. She gradually began to improve and gain strength and flesh, the enlargement of the abdomen to decrease, and the orifice through the rectum to diminish, so that I could hardly insert even the point of one finger, neither could I remove any more portions of bones, as I feared there must still have some remained, although very little enlargement or hardness could be perceived.

In a very short time she came rapidly round, being able to walk about and attend her ordinary household duties. She went off to the sea-side for a month, and returned looking as well as ever, apparently in good health, which she has continued ever since to enjoy.

I thought this would turn out a case of placenta previa, from the constant hæmorrhages, but it was evidently one of extra-uterine pregnancy. I had never met with a case of the kind, and I mentioned it to some of my medical friends, whose experience in such matters seemed little better than my own; so, with care and patience, and using as little force as possible, and avoiding every source of irritation, now and again gently aiding by the assistance of two fingers, everything has gone on well, and the woman is now strong and healthy, and regular in her monthly periods as usual.

Hospital Report.

SURGICAL RECORDS.

By WILLIAM STOKES, Jun.,

SURGEON TO THE MEATH HOSPITAL AND RICHMOND SURGICAL HOSPITAL.

OPERATION OF CASTRATION.

THE two following cases, in both of which I recently performed the operation of castration, present features of considerable interest, whether regarded in a purely clinical or pathological point of view.

CASE I.—CHRONIC HÆMATOCELE OF SIX YEARS' DURATION: DIFFICULTY OF DIAGNOSIS: CASTRATION: DIVISION OF THE CORD BY THE ECRASEUR: ARREST OF HÆMORRHAGE BY THE THIRD METHOD OF ACUPRESSURE.

John C., æt. 67, was admitted into Meath Hospital, under my care, in the middle of last October, suffering from a large scrotal tumour occupying the left side. The history the patient gave of his case was as follows:—About six years ago he observed a considerable enlargement of the left testicle, which came on without any appreciable cause, and up to a few days previous to his admission it was unattended with any considerable distress. One day, however, early in the month of October, while engaged in the laborious occupation of packing hay on a cart, he felt a sudden and violent pain in the tumour, and this was followed two or three days afterwards by a great increase in its size. He accordingly came up to town, and was at once admitted into hospital. The tumour was very large, oval in form, of very great weight, and firm in its consistence. It weighed very nearly four pounds, and was attended with very great pain. The anterior surface of the tumour was smooth, but posteriorly there was considerable irregularity, and at the inferior portion there was a point at which we determined distinct fluctuation. At this point I made a puncture with a fine trochar, and gave exit to about half a pint of a clear sero-sanguineous fluid, not like that of an ordinary chronic hæmatocele, which is usually not transparent and of a brownish chocolate colour, but like what, perhaps, may be best compared to the juice of a ripe cherry. This operation was not attended with any very great diminution in the size of the tumour, not either after a second similar operation, which was performed some three or four days after the first. From this circumstance, therefore, from the great weight, size, and hardness of the tumour, from the marked enlargement of the veins which ramified over its surface, both anteriorly and posteriorly, from its form and irregularity, from the pain in the tumour, and great thickness in the cord, I was led to modify the opinion I originally held, which was that it was a simple hæmatocele, and to suspect at all events that the case was complicated with disease in the testicle. The diagnosis in these cases, especially when they are very chronic, and the tunica vaginalis and its coverings have become very much thickened, is attended with great difficulty, "in some instances," as Mr. Curling observes, "it cannot be satisfactorily made out by the nicest manipulation of the most experienced hands." It was, however, obvious, that whatever might be the precise nature of the tumour, there was but one thing to do in order to relieve the patient permanently from the distress occasioned by it, and that was its entire removal, and the operation was accordingly performed on the 6th of last November. The concluding steps of the operation, the division namely of the cord, and the securing of its vessels, were accomplished satisfactorily; the former by Weiss' new ecraseur, an instrument of which I cannot speak too highly, and the latter by the third mode of acupressure, which succeeded admirably in completely arresting the hæmorrhage. In truth, in no case in which I have practised acupressure, have its good effects been more apparent than in the one at present under consideration. The morning after the operation the needles were removed, and there was no trace whatever of any secondary hæmor-

rhage. A section of the tumour showed that the opinion originally formed was the correct one. The tunica vaginalis was found to be much enlarged, in some places being five or six lines in thickness. It was of a yellowish white colour, and extremely firm and tough. The testicle, which was much atrophied from the long-continued pressure to which it had been subjected, but not presenting any other morbid appearance, was found, as usual, at the posterior portion of the tumour. The coagula, which resembled much the contents of an old aneurismal sac, being connected into a solid fibrinous substance of a yellowish fawn colour, constituted the principal contents of the tumour. Numerous trabeculæ, formed of coagulable lymph, also traversed the interior of the cyst, giving it the characteristic honey-combed appearance, so often met with in chronic hæmatoceles. The remaining portions of the thickened sac of the tunica vaginalis was occupied by an adventitious gelatinous deposit, which was quite transparent and of a dark-red colour, and this occupied, for the most part, the numerous partitions formed by the trabeculæ or bands of coagulable lymph.

During the convalescence of the patient, nothing untoward occurred. The wound healed with greater rapidity than I had at all anticipated, and the patient was able to leave hospital within a fortnight after the operation in good health and spirits.

The following case is also one of much interest, as it presents an example of a disease which is rarely met with, and which, though not true cancer, is eminently malignant in its character.

CASE II.—RAPIDLY GROWING SARCOMATOUS TUMOUR IN SCROTUM, ORIGINATING PROBABLY IN THE CORD : CASTRATION : DIFFICULTY OF SECURING THE VESSELS OF THE CORD OWING TO ITS RETRACTION INTO THE ABDOMEN : LIGATURE OF THE CORD "EN MASSE :" RETURN OF THE DISEASE IN ABDOMEN IN LESS THAN TWO MONTHS : PATIENT STILL UNDER OBSERVATION.

Columb. D., æt. 21, by occupation a farmer, of fair complexion, and very strongly built, was admitted into the Meath Hospital under my care on the 10th of last November, having been recommended to me by my friend Dr. Bewley, of Clara, King's Co. The history he gave of his case was as follows :—He stated that about three years ago, while riding on a very restive horse, he was thrown forwards against the pommel of the saddle. The left testicle was severely struck, and a short time afterwards it swelled, and presented all the usual signs of traumatic orchitis. Under the influence of rest, antimonials, local depletion, and other antiphlogistic measures the inflammation subsided completely, and in a short time the organ did not present any induration or increase in its natural size whatever. From this time up to three months previous to his admission into hospital, he remained in the enjoyment of perfect health. About the middle of last August, however, he observed an increase in size of the testicle, which had three years previously been the seat of the traumatic orchitis. No cause could be assigned for the second enlargement of the gland.

In November, the tumour having reached a very great size, he was recommended to come up to town to seek for surgical advice, and he accordingly did so, and was admitted into the Meath Hospital, under my care, on the 3rd of last December. The tumour was very large, weighing over two pounds. It was globular, irregularly lobulated on the surface, free from pain, and there were two points at which there was distinct fluctuation. Into one of these I passed a fine trochar, and evacuated about two drachms of a clear, straw-coloured, honey-like fluid, which had an alkaline reaction. The lower portion of the cord appeared considerably thickened.

Looking at the history of this case, and the general external characters of the tumour, I could not avoid arriving at the conclusion that it was decidedly malignant in its nature, and that the only chance for the patient was the complete removal of the entire growth. In this view my colleagues concurred, and the operation of castration was accordingly performed on the 7th of last December. As regards the operation, nothing unusual is to be reported about it, excepting the great difficulty I experienced in arresting the hæmorrhage, owing to my being obliged to divide the cord very high up, and this rendered the application of acupressure needles a matter of great difficulty. So great was the tendency of the cord to retract into the abdomen, that three times the needles commanding the vessels slipt off the cord. Abandoning acupressure, therefore, in this case, I seized the end of the cord with a strong forceps, drew it forwards, and ligatured the entire structure *en masse*. This I was enabled to remove on the third day after the operation, and no secondary hæmorrhage followed. During the healing of the wound nothing untoward occurred. It healed with great rapidity, and within a fortnight after the operation the patient was able to return home. On making a section of the tumour, I found that the testicle was imbedded in the tumour, but did not present any morbid appearance. The disease most probably originated in the cord. Dr. Purser, my colleague in the Carmichael School, kindly examined the tumour microscopically for me, and directed my attention to a very remarkable feature connected with it—namely, the appearance of voluntary muscular fibres in the substance of the morbid growth. This is, in truth, difficult to account for. The tumour appeared to Dr. Purser to be an example of the fuso-cellular sarcoma of Virchow, analogous in many respects to the fibro-cellular tumour of Paget. The description, in truth, of the external appearances of this class of tumours, given by the last named eminent pathologist, would answer in every respect to what we found in the tumour at present under consideration, for, on making a section, we observed "opague white bands intersecting a shining succulent basis-substance of serous yellow, or greenish-yellow tint. Through this basis the bands course in circles or wavy lines, or form complete partitions ; or in the smaller lobes of the tumour they run without order, only forming white marks on the yellow ground colour, but giving no appearance of grain, or of regularly fibrous structure."—Lectures on Pathology, vol. ii., p. 107.

For some weeks after the patient's return to the country he remained free from all pain or weariness, and greatly relieved by the absence of the tumour. Towards the end of January, however, he began again to suffer much pain in the lower portion of the abdomen on the left side, and along the spine. Shortly after this he observed a tumour growing immediately above where the cord had been divided, and another higher up on the same side. He then came up to town, and put himself again under my care in the Richmond Hospital, where he is still under observation. Nothing gives him so much relief as the hypodermic injections of the acetate of morphia.

SURGICAL SOCIETY OF IRELAND.

FRIDAY, 14TH FEBRUARY.

Mr. PORTER, Vice-President of the College, in the Chair

DR. HARGRAVE read the following paper :—

REFLECTIONS ON THE OPERATION FOR SECURING THE ARTERIA INNOMINATA AND THE SUBCLAVIAN IN THE FIRST PART OF ITS COURSE, WITH THE PROPOSAL OF A NEW OPERATION FOR EFFECTING THIS OBJECT.

Surgeons are still undecided as to the best operation to adopt for curing aneurisms of the subclavian and arteria innominata arteries. As far as my inquiries enable me to judge, and to collect the result of these operations, the following have been performed on the subclavian in the first part of its course, and all unsuccessful, ten in number : two by our late Professor Colles, the first, I believe, in an historic view, to propose and execute it; Hayden, one ; Liston, two, in one case he also tied the carotid ; Mott, one ; O'Reilly, one; Partridge, one ; Rodgers, one ; Arndt, 2 ; all fatal by hæmorrhage, except Partridge's, whose case succumbed on the fourth day from pleurisy and pericarditis. On the arteria

innominata, thirteen operations have been performed, as collected by Mons. Le Fort, published in the *New Orleans Medical Record*, translated by Dr. Dowler of that city, from Le Fort's paper. The surgeons who performed this operation are: Mott; Arndt, of St. Petersburg; Bland, of Sidney; Græfe, of Berlin; Hall, of Baltimore; Hutin, or Oran; Lizars, of Scotland; Cooper, St. Francisco, twice; Bugalsky, according to Velpeau, twice; Norman, and a surgeon mentioned by Dupuytren, but not named, 13.

Instead of ligature of the innominata, the subclavian and the carotid were tied by Cruveilher, Rossi, Khul, and Liston. To these operations must be added Smith, of New Orleans, who performed, what I consider, a triple operation, by tying the vertebral, and by G. H. Porter, of Dublin, who compressed the axillary by acupressure, and subsequently the innominata by a metallic compressor, and by Fearns and Heath, eight.

Of these thirty-one or two operations but three were successful, all dying from secondary hæmorrhage. This operation has been performed in such a manner as to permit me to classify it into the following varieties:—

1. On the subclavian as a single operation, all of which succumbed to secondary hæmorrhage.

2. Simultaneous operation on the subclavian in the first part of its course, and the carotid, by following Brasdor's proposal, as practised by Rossi, as shown by Heath.

3. Ligature of the carotid alone gives no sufficient hope for success. Mr. Butcher, in the summer of 1863, exposed the right subclavian in the first part of its course for aneurism: it was found enlarged and diseased; he then traced the vessel to its origin from the arteria innominata: its diseased condition interdicted the application of the ligature; he then tied the common carotid about three-quarters of an inch above its origin. In the operation *very little* blood was lost, the patient was doing well in every way, when suddenly, on the fourth day after the operation he became suddenly very faint, and gradually sunk eighty-eight hours after the operation. Mr. Butcher afforded me much gratification in witnessing this operation through its embarrassing steps. A full account of it is given in his very practical work on Conservative Surgery, and cogent reasons assigned for not simultaneously securing the axillary artery.

4. Simultaneous ligature of the subclavian in the third part of its course, and of the carotid above the omohyoid m., by Heath successful, succeeded also in Fearns's case after a long interval between each operation, two years.

5. Smith's operation, New Orleans, May 15th, 1866. A ligature was placed on the arteria innominata, one-quarter of an inch below the bifurcation, another ligature on the carotid, one inch above its origin from the subclavian aneurism; fourteen days after the operation excessive hæmorrhage set in, various local means were tried to arrest it, with intermittent success; finally, fifty-four days after the first operation, the vertebral artery was tied (not a very difficult operation), no return of hæmorrhage, and the patient recovered.

6. Our Vice-President, Mr. Porter's case, recently published, in which the axillary artery was compressed by acupressure on June 20th, 1867, which failed to effect a cure; the arteria innominata on July 31st was then exposed and compressed by an instrument invented by Mr. L'Estrange to compress the vessel, which was followed by profuse hæmorrhage on the 9th of August after the operation on the innominata, and on the day following, the 10th, it proved fatal. The innominata was found to have given way by ulceration and slough, just below the bifurcation of it into the carotid and right subclavian, apparently where the compressor of L'Estrange had been applied, *and on the distal side of it.*

Operation for securing the vertebral artery as practised by Smith, of New Orleans:—

"The head of the patient being thrown back and slightly turned to the left, an incision two inches in length was made along the posterior border of ster. mast. m., commencing at the point where the external jugular vein crosses this muscle and terminating a little above the clavicle, the edge of the muscle being exposed and drawn to the inner side, the prominent arterior tubercle of the sixth cervical vertebra was readily felt and taken for the guide. Immediately below this lies the vertebral artery; a layer of fascia was now divided, some loose cellular tissue with lymphatics, and the ascending cervical artery were pulled to the inner side, and a separation was made between the ant. scal. and longus colli muscles, close between their insertion into the tubercle when the artery and vein became visible, the latter was drawn to the inner side (this is important), and the needle passed round the artery from without inwards."

To render this operation doubly secure, I may mention some irregularities I have myself met with. For example, I have seen the artery enter the foramen of the fifth cervical vertebra, and in two instances it ascended along the neck, parallel to the carotid, almost equalling it in size, but *external and posterior* to its entering into the foramen of the third cervical vertebra; such irregularities would appear to me to facilitate the operation for securing the vessel.

Every candid surgeon must admit that all these operations have been performed with consummate skill, and specially the last case of this operation recorded by our Vice-President, Mr. Porter, my friend and former pupil, who so successfully surmounted great difficulties in securing the arteria innominata, and placing a *metallic* compressor upon it, thus meriting the blue ribband in operative surgery. I specify this compressor in contradistinction to the presse artere used by Crampton, and others, which was partly metallic and partly a narrow piece of tape.

From such a history of this operation, and its fatal results, giving but three successful cases, surgeons are justified, I would add, called on to consider if any other operation or modification of operation can be adopted to secure a more general success. The danger to be guarded against is the hæmorrhage at no very remote period following the operation, which should not surprise us when we consider the large vessels which permit a recurrent flow of blood to the aneurism on the distal side of the ligature, almost immediately after it has been applied either to the arteria innominata, or to the subclavian in the first part of its course, thus maintaining the disease and favouring uncontrollable and fatal bleeding. Mr. Smith's bold and decided practice has indicated from whence the bleeding will occur; it is evident from his case that the operation for the subclavian artery in the first part of its course, should consist of a double operation simultaneously performed on the subclavian, or the arteria innominata, and the common carotid; should subsequent hæmorrhage occur, then to secure the vertebral artery without loss of time.

The operation, which to me is not only feasible, but worthy of testing, is the following one—first, to expose the subclavian in the first part of its course, or the innominata, and to pass the ligature round the vessel, then to saw through the clavicle about its external fourth; my object in encircling the artery with the ligature before the section of the bone is made, is that we cannot predicate what disturbing influences in the relations of the parts will follow it; they might be considerable or nothing, we guard against any untoward result of such section, by acting as suggested as regards the ligature than tie it. By this proceeding, when the shoulder is deprived of its support by the clavicle it approaches to the thorax; the consequence of which is that the tension of the artery is relaxed, the vessel and the ligature are at rest, not disturbed by any of the motions of the shoulder, and no risk of the vessel being in any way lacerated and giving rise to hæmorrhage is obviated. By referring to the dead subject, or, in place of it, the anatomical plate representing the course of the subclavian, it will be seen what little support it receives from the surrounding tissues; in fact, it represents a tense full tube, extending from its origin, and resting more or less on the apex of the pleura costalis, till it reaches the first rib, and is not well supported by soft parts till it is escaping from beneath the clavicle into the axillary region. By adopting this plan for securing the subclavian by a single operation, it guarantees, as far as operative surgery can effect perfect quietude, and less tension to the vessel after the ligature is applied to it. It can be urged against this proposal that the injury to the clavicle is a great objection, complicating it by producing a compound fracture of that bone; it must be borne in mind that this lesion is made in the most cautious and careful manner, admitting that osseous union does not follow it, still the patient will have very great, almost perfect, use to the upper extremity in all its motions.

One word as to the kind of ligature for large arteries. From my experience of its value on the common iliac artery, no better ligature can be used than that of hemp, *from the firm way in which it remains on the artery, the complete absence of irritation, and no alteration in its strength and soundness.*

It is almost unnecessary to state that Sir Wm. Fergusson is not in favour of operation on this vessel. Liston was also unfavourable to it. Guthrie says—"It is probable, if the operation be repeated, it will ultimately be successful, although it must always be exceedingly hazardous," a prudent and practical obser-

vation. As to the proposal of sawing through the clavicle, as proposed by me in my work on Operative Surgery for Ligature of the Subclavian, when buried deep behind an elevated clavicle, Mr. Erichsen says—"The most serious objection that can be raised against this practice is the fact of the clavicle being sometimes a part of the wall of the aneurism, but supposing that the surgeon can satisfy himself that this was not the case, I cannot see any objection to this procedure, provided any great and insurmountable difficulty presented itself in getting the ligature round the vessel without it." These, *ipsissima verba*, are repeated in the last edition of his most practical work on Conservative Surgery.[1]

Of all these six operations which I have brought before the Society, whether upon the cardiac side of the aneurism as a single operation, or upon the distal side of it, complicated with operations simultaneously performed, or subsequently upon arteries communicating with the subclavian, as the carotid or vertebral, only three out of thirty-one have been successful—Heath's simultaneously performed on the distal side of the aneurism and the carotid; Fearns's case of double ligature.

Three operations have been considered as successful, Fearns's, Smith's, and Heath's; in reality but two were immediately successful, Smith and Heath, while Fearns's operation consisted of two at long intervals: the common carotid was first tied, then the subclavian after an interval of two years. The patient, a female, lived two years and three months after the ligature on the carotid, and sixteen weeks and five days after the subclavian had been tied.[2]

It may not be uninteresting to mention the periods at which the ligature came away as recorded in some of these operations.

In Smith's case the ligature on the carotid came away in 13 days; from the arteria innominata in 14 days, then followed by profuse hæmorrhage.

In Mott's case of arteria innominata the ligature came away on the 14th day, the patient living to the 26th day.

In Mr. Porter's case the hæmorrhage also occurred on the 14th day after the operation on the arteria innominata, proving fatal on the following day. In Græfe's case the patient survived the operation for 67 days.

It is an interesting fact so carefully noted by these surgeons, Mott, Smith, and Porter, that the hæmorrhage took place on the 14th day after their operations; and Smith's case of the double-simultaneous operations on the arteria innominata and carotid, then the vertebral to arrest secondary hæmorrhage.

Out of the thirty-one cases there have been twenty-eight failures, a very discouraging result; still we should not abandon this operation, and if surgeons decline to adopt and perform the operation now proposed and brought before the Society; they can avail themselves of that valuable and most instructive operation of Smith, of New Orleans—to secure the arteria innominata and carotid simultaneously; *should secondary hæmorrhage occur not to waste time in futile and useless efforts to arrest it by hæmostatics;* but directly appeal to the vertebral artery and secure it. By such a procedure all the great collateral vessels are secured and the hæmorrhage arrested, and the patient saved. From the cases recorded, secondary hæmorrhage always resulted from the distal side of the ligature, or compressor, caused by the re-establishment of the circulation in the large vessels, of which the vertebral must be considered the principal one, if not the only one, after the carotid and arteria innominata have been secured.

Owing to inattention to these remarkable arterial communications with the subclavian, surgeons were not prepared to act, and to adopt the only means afforded them by their profession when hæmorrhage occurred, which always took place on the distal side of the ligatures or compressors, and to secure the vertebral artery.

In conclusion, I am strongly of opinion that the section of the clavicle, as now proposed, prevents the laceration of the artery and the consequent fatal hæmorrhage; also to secure the common carotid artery for greater security.

I have brought this operation before the Society to elicit their opinions, and to advocate further inquiries to make it, if possible, more available to the Profession, as the surgeons in this city have been so successful in the treatment of aneurism.

The CHAIRMAN said they would all agree with him in thinking this a most valuable communication, on a subject always interesting to an Irish surgeon. With respect to sawing across the clavicle, he had no doubt it would be a most useful proceeding in some cases. In his own case, to which reference had been made, he had a chain-saw beside him, and was fully prepared, if he found any difficulty in passing the needle round the vessel, to cut across the clavicle. He was sure the point which Professor Hargrave dwelt on, that of relaxing the vessel, was a very important one. He believed that in many cases, hæmorrhage was first induced by a sudden strain on the vessel, in the place where it had been weakened by ligature. He would be glad to hear what any member of the Society had to say on the subject.

Mr. STAPLETON said it was very well-known, that cutting across the clavicle might help the surgeon in finding and in tying the vessel, but as to taking the strain off the vessel it did nothing; because, according to the cases correctly reported by Professor Hargrave, the hæmorrhage always occurred from the distal side. He granted, that in large aneurisms cutting across the clavicle might facilitate the mere operative process, but that did not prove that it would prevent secondary hæmorrhage. He thought the great improvement was that introduced by the New Orleans surgeon, in cutting off the recurrent hæmorrhage by securing the arteries from which it came. He repeated that it was not from the proximal end the hæmorrhage came, but from the distal end, and to prevent that was the great aim of the surgeon at present.

The CHAIRMAN observed that the chief point on which discussion was desired was the best mode of preventing hæmorrhage if possible. The hæmorrhage from the distal end was the point before the society.

Professor HARGRAVE in reply said, he thought the operation introduced by Mr. Smith, of New Orleans, was a most useful one in these cases. The hæmorrhage takes place from the distal side, and this was easily understood, for the vessel was scarcely well secured, when they had the recurrent circulation coming down in the carotid and vertebral, and preventing the formation of a clot, so that if they were to succeed in this operation on the subclavian artery, they should be prepared to secure the vertebral artery. Many gentlemen said that they should not perform this operation; but in his opinion they were justified in attempting it, when they saw an unfortunate man, in other respects healthy and of good constitution, suffering from a *most distressing state of dyspnœa*, and calling for anything to relieve him. In such a case he thought that by dividing the clavicle, tying the subclavian, and if necessary securing the other vessels, they put the man in the best position possible under the circumstances. He might not hear or witness it, but he was satisfied that one or other of these operations would be ultimately adopted by the profession.

Mr. STAPLETON—Why not tie all the arteries at once?

Professor HARGRAVE—Because I don't know that the man would not recover without it. I would first tie the subclavian and carotid, and if secondary hæmorrhage came on I would tie the vertebral artery.

(To be continued.)

MEDICAL SOCIETY OF LONDON.

MONDAY, FEB. 10, 1868.

Mr. HENRY SMITH, President, in the Chair.

MR. FRANCIS MASON showed a piece of necrosed bone that he had removed from the left tibia of a patient at the Westminster Hospital. The specimen was about four inches in length, and included the complete circumference of the bone. The patient was a man aged forty-six, who was well until eighteen years ago, when he fell from an omnibus, and sustained a compound fracture of the left leg, and a simple fracture of the right. He quite recovered, and remained well until three months ago, when, without apparent cause, acute inflammation of the left leg came on, terminating in an abscess and complete death of the bone. Mr. Mason brought forward the case as a rare pathological specimen, the whole circumference of the bone having been thrown off. Mr. Mason said the patient was going on perfectly well, and he promised that he would show him to the Fellows of the Society when he was sufficiently recovered.

The PRESIDENT exhibited a young man on whom he had performed excision of the knee-joint six months previously. The patient remained in the hospital three months, and was discharged well with fibrous anchylosis, and only able at that time to move about on crutches. This union was now quite firm, and the limb well developed. The patient was requested to

walk up and down the room, which he accomplished without the slightest assistance, and with the utmost facility, wearing an ordinary boot. The President also showed the bones taken away in an excision of the knee-joint he had operated upon a few days before. There was great thickening of the synovial membrane, and ulceration of the cartilage on the head of the tibia, a thinning of the same tissue on the end of the femur.

Dr. THOROWGOOD then read a paper on

REMEDIAL MEASURES IN ADVANCED PHTHISIS.

The first part of the paper drew attention to the fact that life is often prolonged far beyond expectation in cases in which cavities have existed for some time in the lungs. In illustration, notes of cases taken chiefly from among the out-patients at Victoria Park Hospital were given in detail. In respect of treatment, a good deal of stress was laid on a dry and bracing atmosphere, and in avoiding all places which were reputed damp or relaxing. Confinement in one room was spoken of as a very pernicious practice, as then the patient is poisoned by the exhalation from his own diseased lungs. Among medicines, the hypophosphite of lime was highly commended; iron was spoken of as being useful when there was obvious anæmia. The pancreatic emulsion had been used in a few cases with advantage. The author then spoke of the eliminative treatment, so as to oxidise and eliminate effete matter collected in the blood, and concluded by exhorting the medical practitioner not to use one routine method of treatment, but to consider the merits of each case, and to apply the ordinary principles of pathology so as to unravel the morbid phenomena, and then bring about a more successful plan of treatment.

In the discussion that followed, Dr. CHOLMELEY said he had great faith in bicarbonate of potash in those cases in which the digestive organs were deranged.

Dr. WEBSTER spoke at length as to the reputed value of different climates for phthisical patients, and thought Cannes and Pisa by far the best places. Pau, he said, was too moist an atmosphere.

After some remarks from Dr. Sansom, Mr. Marshall, Mr. Francis Mason, and the President, the meeting adjourned.

TO OUR SUBSCRIBERS.

THOSE gentlemen who pay their Subscription in Advance, at the reduced rate of £1, 1s. 8d., will oblige by kindly forwarding the same for the present year, on or before 25th March inst. Subscribers who have not paid for the past year, are respectfully requested to remit the usual amount, £1, 2s. 6d., either by Cheque or Post-Office Order.

REGISTERED FOR TRANSMISSION ABROAD.

THE MEDICAL PRESS AND CIRCULAR *is published simultaneously in London, Edinburgh, and Dublin, every Wednesday morning. Price 5d. Stamped 6d.*

By Post to Annual Subscribers, £1 2 6

„ *If paid in advance,* 1 1 8

*** Post-Office Orders and Cheques to be drawn in favour of CHARLES COOPER, 3, Lincoln-place, Dublin.

MACLACHLAN & STEWART, South Bridge, Edinburgh.

A. A. TINDALL, 20, King William-street, Strand, London.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 4, 1868.

MEDICAL REMUNERATION.

THE twentieth annual report of the Manchester Medico-Ethical Association comes to us at an opportune moment, and we, therefore, have much pleasure in giving an outline of the doings of this modest but influential Society. For twenty years it has watched over the interests of the profession in Manchester, and exercised in cases of dispute between medical men, or of alleged wrong-doing, the function of an impartial tribunal of arbitration. How well and how moderately it has exercised this high office may be judged of by the fact that its decisions seem to be in all cases respected beyond the circle of its own members. It is gratifying also to find that the balance at the bankers is really substantial.

Sir JAMES BARDSLEY, many years the President, has retired from that post, and Dr. NOBLE succeeds him. Of the questions that have engaged the attention of the Society during the past year, we are not surprised to find that the appointment of a Medical Officer of Health for Manchester should be commented upon in the report, which very properly condemns the modicum of remuneration that has been proposed to be offered, in the following terms:—

"Considering the fact that there are probably not twenty men in England who have, as yet, the special qualifications required for the office, and that it is proposed to offer for the exclusive use of his services a salary less than is frequently paid to a responsible clerk in a Manchester warehouse, it is likely that the benefit of the appointment will not for some time to come be very apparent."

Here is a practical commentary on the competition for the honour of serving the public for nothing, which has reduced so many members of our profession into the instruments of so-called charity on behalf of others!

It is the same story in every department of medical labour. The habit of gratuitous work has become so ingrafted into our daily life that we are in danger of complete decay. The parasite flourishes luxuriantly at the expense of the noble plant which droops for want of the juices of which it is thus robbed. Whence otherwise the cry of poverty which constantly assails us from our ranks? Is it not time to call to mind the proverb that "true charity begins at home?" and to warn those who lavish their gratuitous advice on the public, that they may thereby be taking the bread from the mouths of less fortunate professional brethren and their wives and children?

Unhappily, the habit of giving advice *gratis* has another evil effect. It depreciates the value of all professional service, and thereby makes the public indifferent to the welfare of their medical men. It also tends to lower the scale of remuneration in other grades, until it has reached a point upon which it is impossible for men of education to eke out a livelihood. At Birmingham a great commotion has been made by the club doctors declining any longer to starve upon the paltry pittance offered them by well-to-do artizans. Nor is it only in the capital of the midland counties that a movement for redressing this wrong has commenced. Everywhere the same evil is felt, and the same complaint made. For months the medical journals of the three kingdoms have teemed with the injustice of existing customs, and urged more or less radical remedies.

The manner in which this question is viewed by such a body as the Medico-Ethical Association of Manchester is therefore full of interest. The report we have already cited says:—

"The question of the remuneration of Surgeons to clubs, which is at present engaging the attention of various other bodies, came under the notice of the committee also, and a circular was issued to the members of the profession in and around Manchester requesting their opinion on the present rate of remuneration in this district—on what they would consider to be an equitable rate—and on their willingness to co-operate in securing the adoption of the latter. About forty gentlemen only replied to this circular, but these were unanimously of the opinion that the present rate of payment is totally inadequate and unremunerative. It will lie with the future committee to see what further steps can be taken, but

this much may with confidence be affirmed, that as long as there is so little public spirit or self-respect among many members of the profession that they will give their time, and skill, and the requisite medicines, at rates lower than would be charged by any respectable druggist for the last alone, there is little hope of amendment. This is the more deeply to be regretted because the ordinary laws of political economy ensure that, in the long run, it is the mass of poor and ignorant labourers who are the real sufferers, rather than the few educated medical men whose services they think to obtain at a cost so absurdly below their real value."

The evil is here laid bare and the case stated without any attempt to influence the reader otherwise than as a natural effect of the facts. For this reason we have thought the passage worth quotation, and we urge it upon the attention of our readers as one of the utmost importance.

We are by no means disposed to interfere with the ordinary laws of political economy; we would not place professional combinations in a different class from trades'-unions; we are no bigoted advocates of professional interests as superior to those of the general public; we are content with our natural position as a skilled and highly-educated section of society; we do not call for protective legislation; we ask no endowment, no patronage. But we do hold that in our department, as in every other, "the labourer is worthy of his hire." No other class toils unrewarded as we do. Who ever heard of honorary solicitors, or advice-gratis-giving-barristers? Does the chaplain for the honour of his calling minister for nothing? Yet, the public takes it as a matter of course that medical aid to every charity is to be had for nothing, and throughout the provinces clubs that can vote enough beer-money at every meeting to make it a profitable speculation for the tavern-keeper, or can squander many weeks' wages in a contest with masters as to the number of apprentices that shall be instructed, are not ashamed to ask medical men to accept remuneration which any of their members would scorn to take. They are quite eloquent as to the increase in the price of all commodities during the last few years, which has the effect of making their wages provide less; but assume a tone of surprise when the surgeons of their clubs remind them that they too have a right to live by their labour, and that the remuneration hitherto given has scarcely paid for the drugs supplied, much less left a margin for the toil they have undergone. It is time the profession spoke clearly and distinctly upon these points. The public must be clearly given to understand that great as is our love of science, and overflowing as are our hearts with sympathy with the sick, these feelings will not keep the "wolf from the door." It has long been a vice of English society of every grade, from the peer to the pauper, to undervalue the aid we offer. We have known the highest nobles ungenerous to their attendants, the wealthiest often require reminding of the fees they should hasten to offer; in the middle and lower middle classes the "doctor's bill" is proverbially put off till the last, and the pay of the working man's club doctor is in some parts on a level with that of those great sacrifices to humanity, the poor-law medical officers of this enlightened and wealthy community.

Birmingham and Manchester have done wisely to speak in unmistakable tones. We add our voice to theirs, because the great mission of the journalist of a scientific and learned profession cannot be adequately carried on while that profession, as a whole, is ground down with poverty. What is the advance of the medical art to men whose lives are passed in a desperate struggle for food and raiment? How shall the patient exploration of nature's secrets be carried on if the explorers have to spend more than the average of human energy on obtaining their daily supplies?

Foolish, selfish public! Your best friends neglected, forgotten. Your most faithful servants left with their wages unpaid; nay, when those servants venture to ask for payment, not only is it withheld, but they are ordered to go on working for nothing. Heavier tasks are laid upon them; they are commanded to make bricks without straw; they are reproved for murmuring, and expected to bless the hand that finds them work, but withholds from them bread. Foolish, selfish public! This cannot long continue. The cruelty must recoil upon the head that devises, and the hand that executes it. You may exterminate your servants, and then what will you do? When this generation ceases from its labours you may find none others to take their places, and then you may put your trust, or not as you please, in the mountebanks you now often reward more richly than those whose whole lives are passed in disinterested devotion to science. Plodding on in patient daily toil, intent on discovery chiefly, the medical philosopher of this age may perhaps discover that the hope of living by his labour is vain, that a grateful public will allow him to starve; and that, therefore, his best plan will be to adopt some alien pursuit as a means of obtaining his livelihood, and furnishing him with those necessaries for scientific work, which the practice of medicine no longer supplies.

THE LATE LUNACY CONVICTION.

THE conviction of Mr. SHAW, on the prosecution of the Commissioners of Lunacy, for illegally receiving into his house, for profit, lunatic patients, demands the attentive notice of the profession and the public. In the first place, it cannot be forgotten that this prosecution differs *toto cælo* from several upon which we have had occasion to comment, inasmuch, as a charge was made upon the evidence of most respectable witnesses of cruel treatment and neglect such as the Act is designed to prevent. The Commissioners, as we have frequently pointed out, are bound to prosecute wherever they find that the letter of the law has been infringed, but they have invariably shown themselves lenient, when a mere inadvertency has exposed to this ordeal gentlemen who have treated their patients with humanity and skill. They would be guilty of a gross dereliction of duty, did they not press for the utmost rigour of the law whenever they have reason to believe that unhappy lunatics have suffered captivity and cruelty at the hands of men who have allowed cupidity or neglect to overcome their better feelings.

The first indictment under which Mr. SHAW was prosecuted, alleged that the patient, Mrs. WESTON, was made to perform menial work in the prisoner's family, and the case was so clear that Mr. Serjeant BALLANTINE, who was retained for the defence, consented to a verdict of "guilty."

The second indictment was much more serious. It not only laid to the prisoner's charge the reception of the lunatic, Mr. CLODE, but charged wilful neglect of that patient. At first, £60 per annum was paid for Mr. CLODE, but after that £120. Still it seems that no amelioration took place in the unfortunate patient's condition. Dr. BLANDFORD and Dr. BENNET were sent by the Commissioners to examine the patient, and the description they gave of the state in which they found him, exceeds every-

thing we have heard of for many years. The room in which the patient was found had no fireplace; it was only about 12 feet square, and 6 feet in height. The man occupied a straw mattress; he had nothing on except an old flannel shirt, and a piece of carpet flung over him. These were in a most disgusting state, reeking with filth and excrement, and unfit to be touched except with a pitch-fork. The smell of the room was overpoweringly nauseous, although the patient was so far lost to his state as to say he was "quite comfortable."

It is not surprising that such evidence sufficed to insure a conviction in spite of the attempt to raise a discussion as to the difference between lunacy and unsoundness of mind. At the conclusion of the case for the prosecution Mr. Serjeant BALLANTINE confessed that he was virtually without a defence, since, after carefully watching the evidence, he could not contradict it.

Of course a verdict of "guilty" resulted in both cases, and it was in consequence of the peculiarly heinous nature of the whole transaction that the LORD CHIEF JUSTICE expressed with such force the sentiments that will find an echo wherever they are read.

We deeply regret to be called upon to epitomise such a case. There is something particularly revolting in the idea of ill-using a person unable to take care of himself, and one case like this makes a deeper impression on the public than the thousands in which our lunatics are surrounded with every comfort. But the very fact that there is little likelihood that another instance of the kind will soon recur, renders it the more imperative upon us to notice this instance. The feelings produced upon us by perusing the trial have been so well expressed by the LORD CHIEF JUSTICE that we have no hesitation in appending his remarks by way of concluding this disagreeable summary. In passing sentence he said:—

"You have been convicted upon two indictments, and I must say I consider the case is a very serious, and indeed, an aggravated one. The case of Mrs. Weston is one of an undoubted lunatic. The statute is a most salutary one; the protection it gives to lunatics is most valuable, and it is essential that it should be zealously upheld. And, as to the first case, you have broken this salutary law, and have done so knowingly and wilfully. It appeared that you put this poor lady to menial work, and, having received her as a patient, you treated her as a servant. I feel that I must pass a severe sentence. And the sentence upon you in the first case is, that you pay a fine of £100, and be imprisoned for two months, and until the fine is paid. As to the other case, I dare scarcely trust myself to speak of it. The evidence can leave no doubt as to the miserable condition in which that unfortunate man was allowed to be, with your knowledge. And what makes the case infinitely worse is, that you claimed and received a double rate of remuneration for his care and maintenance, and, so far from expending a single shilling of it in the promotion of his comforts, you allowed him to go from bad to worse, until he lay, so to speak, wallowing in his filth in the abominable condition we have had described. It is a most aggravated and scandalous case. A point of law has been raised and reserved on this case of which, if it is determined in your favour, you will have the benefit; and in that case will escape punishment imposed by law, though I should hope your own conscience will not leave you wholly unpunished for conduct so utterly discreditable to you either as a man or as a Christian. It is my duty, however, to pass sentence upon you for the offence of which, in this instance, you have been convicted; and the sentence is that you be imprisoned six months and pay a fine of £100, and be imprisoned until it is paid."

INSPECTOR-GENERAL MOUAT, V.C., C.B.

THE *Gazette* of the 3rd instant contained an announcement that this distinguished officer, lately the head of the Army Medical Department in Ireland, had been placed on half-pay, and as there is, as it seems to us, much injustice in this quasi-censure on Mr. MOUAT, we have taken the trouble to make ourselves acquainted with the facts of the case.

Mr. MOUAT has been about 30 years in the army, and has spent 22 years of that time abroad. About 18 months ago he returned from foreign service, and not many months afterwards he was placed at the head of the Irish Army Medical Department. Recently he was called on to proceed to India to fill the most lucrative post in his line.

He asked for respite on the score of health, as recommended by a Medical Board, at the same time offering to proceed as ordered if the officer next on the list declined to submit to the infliction of £3000 a-year. He is admittedly a most effective officer in his present or late position, and he is not a valetudinarian. Yet he has been placed on half-pay, notwithstanding his readiness to proceed according to orders, and, as report has it in Dublin, for some unworthy reason to which we do not care to refer more particularly at present.

A reference to Hart's Army List will show that Inspector-General MOUAT has been 30 years in the service, as we have already noted—that he is one of the most distinguished Medical Officers in it, having been repeatedly mentioned in public dispatches, promoted for merit, and honoured with special marks of the Royal approbation; in fact, his services, embracing as they do the medical charge of the large field hospital for wounded in the Crimea, and responsible charge of a large army in the field in two subsequent campaigns, so far exceed that of the present head of the medical department, and all his predecessors, except Sir J. MACGRIGOR, that it is difficult to understand how an officer of such marked and conspicuous merit can be subjected to so great an injustice as compulsory half-pay. There must be something very wrong in such a system, and Dr. LOGAN is bound to satisfy the medical profession that the interests of the public service required, and the circumstances fully justified, so unusual, arbitrary, and tyrannical a proceeding as forcing an officer on half-pay, both able and willing to proceed anywhere, and who has not been accused of any misconduct. He is also bound to quote the apocryphal rule or regulation of the service under which this has been done, and to state if it has ever been promulgated to the army, and if not, why it has been withheld. If old officers, of such standing as Mr. MOUAT, are to be subjected to such harsh and ungrateful treatment, what must be the fate of the juniors under such a regime? Medical candidates would do well to consider their future, before undertaking service under such circumstances.

We feel persuaded that if the attention of his Royal Highness the DUKE OF CAMBRIDGE be called to this injustice to Mr. MOUAT, he will see it rectified speedily and effectually. At any rate, the House of Commons is open, and we hope some independent member will see to it that the Director-General answers for his stewardship in this matter. At present the case seems to be verily this—"One soweth, and another reapeth."

Notes on Current Topics.

The Public Health.

THE deaths registered in London in the last week were 1266. The average number for that, the ninth week of the year, with the necessary correction for increase of population, is 1551. The health of the metropolis, therefore, continues satisfactory, the mortality being during the week 285 less than the weekly average. There were only 252 deaths from zymotic diseases, the average number being 321. We regret to notice among these 18 deaths from small-pox. There were, further, 22 from measles, 23 from scarlatina, 9 from diphtheria, 55 from whooping-cough, 50 from fever, and 13 from diarrhœa.

Consumption caused 144 deaths, bronchitis 138, pneumonia 74, disease of the heart 50.

The annual rate of mortality in the week was—in London 21 per 1000, in Edinburgh 31, Dublin 27, Glasgow 33, Bristol 26, Birmingham 27, Liverpool 29, Manchester 32, Salford 28, Sheffield 20, Leeds 24, Hull 27, Newcastle-on-Tyne, 23.

Hope for Liverpool.

LAST week, the Town Council of Liverpool gave the Health Committee authority to borrow £71,000. This sum is to be devoted to sanitary improvements. One of the first works undertaken will be the conversion of privies into water-closets.

We trust this may be the beginning of a time in which the health of the townspeople will be one of the first considerations of the local authorities.

Officer of Health for Manchester.

MR. LEIGH has been appointed Medical Officer of Health for the city of Manchester, at a salary of £500 per annum. It is time, indeed, that some such appointment should exist, for Manchester has long been in anything but a satisfactory state. Last year the death-rate rose to 31·4. The annual death-rate during the last nine weeks of the present year averaged 31·6 per 1000, against 33·3, 34·6, and 33·1 in the corresponding nine weeks of 1865-6 and 7. Last week the proportional number was 32·1 per 1000; the death-rate being augmented by scarlatina, whooping-cough, and the typhoid forms of fever. The deaths of children under five years of age constitute about half the total mortality of the city. When the annual rate of mortality in Manchester was 34·8 per 1000 of population, then, out of 10,000 children born, 5121 were boys, and 4879 were girls; and 3609 boys and 3703 girls were alive at one year of age; therefore, 1512 boys and 1177 girls died in the first year, or out of 10,000 children born, 7312 were alive at age one, 2689 having died in the first year. At age five, out of 10,000 children born, about 5145 were alive, 4855 having died before attaining that age. In England and Wales, out of 10,000 children born, it is found that 8505 are alive at age one, 1495 having died in the first year. At age five, 7368 are alive, 2632 having died before attaining that age.

These figures clearly show that the City Council ought long ago to have taken this step. We hope to find that amelioration will shortly follow the appointment of a competent officer.

Starved under the Poor-law System.

LAST Thursday, Dr. Lankester held an inquest on the bodies of two boys who had died of starvation. The case was a very sad one. The father, a whitesmith, was ill, and so unable to follow his work. His wife, on applying for assistance at St. Pancras Workhouse, was reproved—told "that as her husband was a whitesmith she should not ask for relief." This witness stated that this "was after the poor fellow had been out of work for six months and ill." We should like to hear from the official who thus reproved this half-starved wife, who, in his opinion, should apply for relief. There was abundant testimony of the man's needs, yet he was deprived of the relief provided by the law of the land for such as he. In consequence of this his two boys were actually starved to death. Is it not time to try some of the poor-law officials for manslaughter?

This poor sick whitesmith was offered work in the stone-yard at 9d. per day, but could not do it. Other help was denied unless he and all his family would go into the workhouse. As the poor fellow sometimes got a job by which he earned a few shillings, he postponed this fate as long as possible, and from his inability to buy them food enough his two boys died. He kept out of debt, but could not feed his family; so the humane poor-law officials let them die. England may well boast of possessing a poor-law.

The Sick Poor in Workhouses.

AT a meeting of the Association for improving Workhouse Infirmaries held last Friday, a general opinion was expressed that it would be desirable to take steps to obtain a Parliamentary inquiry into the whole subject. It also transpired that a man who had been obliged to resign the mastership of a Workhouse had been appointed to the same post in another Workhouse, and that the Poor-law Board had given its sanction. It was understood that a member of the Association would put a question in Parliament in reference to this case.

Lady Nurses.

IT is greatly to be regretted that the organisers of the system of nursing by a class of persons superior to those hitherto employed in hospitals, have not kept before them the principle most essential to the practical working of the system—the distinct subordination of the nurses to the medical officers. Such a position does not imply the least degradation, it is simply and manifestly necessary to the discipline of an hospital, and it is for want of such an explicit understanding that the lady-nursing system has, so far as it has been tried, broken down. A nurse who entertains, and perhaps expresses, her own opinion about the treatment of the case which she may be called upon to attend, cannot be a good nurse, for she may have no confidence in what she is directed to do, and very probably may convey that absence of confidence to the patient. As long as lady nurses are not responsible to the medical attendant, but only to the lady superintendent, who naturally feels herself bound to take the part of her subordinate in case of complaint, so long must the relation of the doctor and nurse remain unsatisfactory. It has proved to be a source of the greatest discomfort and irritation in the military service, and as long as it is found to be so, it will never be cordially adopted by the hospital surgeons.

Signing Lunacy Certificates.

ON the Northern Circuit last week, a person was tried for signing a certificate of lunacy without being duly qualified. In the certificate, according to the daily papers,

he described himself as a "Physician and Member of the College of Surgeons of Glasgow." He was acquitted. It is well enough known to our readers that there is in Glasgow only the "Faculty of Physicians and Surgeon," that could be with any approach to sense thus described. The point in the case which saved the accused, seems to have been that the signature of the prisoner was not properly proved, whereas he had a brother in practice who could legally have signed the certificate. We recommend the highly respectable Faculty of Glasgow to make inquiries. Meantime, we cannot help thinking that the lawyers have evinced great carelessness or great ignorance in their management of the case. Surely it would not have been difficult to show if the person accused really signed the certificate, and if so, whether he was entitled to do so. Otherwise, what is the use of the Medical Register?

The Study of Mental Disease.

We understand that the initiative of special arrangements for the study of mental diseases has been taken by the University of Cambridge. Dr. Mackenzie Bacon, the Superintendent of the County Asylum, Fulbourn, has been appointed to deliver a systematic course of instruction in this department of medicine, and opportunity will be afforded for clinical experience in the various forms of mania within the asylum.

New Books.

The issue of medical publications within the last month has been small in number and uninteresting in character. But two new works have issued from the medical publishing houses of London. Mr. Coulson's expected work on "Stone in the Bladder, with special reference to its prevention, early symptoms, and treatment by lithotrity," appears as an octavo of 142 pages, issued by Messrs. Churchill, at the price of 6s., and Mr. Balmanno Squire presents the profession with a "Manual of the Diseases of the Skin," with coloured plates, in a post octavo volume of 300 pages, at 24s.

In reprints and later editions we have Sir Henry Thompson's "Diseases of the Prostate," its third appearance. It is issued by the Messrs. Churchill as an octavo of 370 pages at 10s. Mr. Chavasse also publishes in the same form the ninth edition of his "Advice to a Mother on the Management of her children."

From Scotland, a good *brochure* by Dr. James B. Russell, on "Stimulation in Typhus, with incidental remarks on its natural history," is published at half-a-crown, by Maclehose, of Glasgow. Sir J. Y. Simpson's proposal to stamp out small-pox appeared early in the month as a shilling pamphlet from the firm of Edmondston and Douglas, and created, as our readers are aware, much interest.

Messrs. Fannin, of Dublin, have just issued, in large octavo, with two lithographic illustrations, Dr. Henry Wilson's "Lectures on the Theory and Practice of Ophthalmoscopy," portions of which have already appeared in the *Dublin Quarterly Journal of Medical Science*.

We have from New York two translations from the German—Klob's "Pathological Anatomy of the Female Sexual Organs," an octavo of 320 pages, at 14s.; and Dr. Tobold, on "Chronic Diseases of the Larynx," at 16s.

From France is issued "Lorain on Cholera," a study in clinical medicine and pathological physiology," at 7s.

Representation of the London University.

The leading Conservative graduates have determined to make further inquiries as to the strength of their party, with a view of bringing forward Professor Miller as their candidate. Himself a medical graduate of high scientific attainments, there can be little doubt that his candidature will be favourably received by those graduates whose political opinions are in accordance with his own. The leading medical graduates of Conservative tendencies will undoubtedly support him, and should this party be able to carry the election a medical man may be returned for the University.

Should the Conservatives find that there is little chance of success, we understand that they will support Mr. Lowe as the most conservative of the other candidates. But if politics are not quite harmonious, should not the electors of such a constituency give science further consideration? We are informed that some preliminary meetings will shortly be held with a view of deciding upon the question of bringing forward Dr. Miller.

The Medical Arrangements of Dublin University.

The arrangement which we announced last week under which Mr. Butcher is transferred from Mercer's Hospital to Sir Patrick Dun's is thus announced by the authorities:—

"Dr. Butcher has been appointed by the Board of Trinity College to teach practical and operative surgery to the medical students of the College in Sir P. Dun's Hospital, commencing from 25th March, 1868."

The following regulations have also been announced for the guidance of candidates for the University degrees in medicine and surgery:—

"The candidates at the previous medical examination, and for medical degrees, are liable to examination in physics—(viz., heat and electricity), as well as in chemistry.

"The candidates for medical scholarships are liable to examination in the elements of comparative anatomy, as well as in human anatomy.

"The examination for degrees in surgery will in future extend over two days, and be conducted by a court of five examiners, of whom one, at least, shall examine specially in operative surgery."

Dr. James Wharton, Surgeon to the Meath Hospital, and Lecturer in Surgery in the Ledwich School of Medicine, has been appointed Examiner in Surgery in the University in conjunction with Mr. Adams, the University Professor of Surgery, and with Mr. Butcher.

The Late Sir J. Gibson.

Sir James Brown Gibson, K.C.B., M.D., late Director-General of the Army Medical Department, has died at the age of 63. He had risen through the various grades to this high office, having entered in 1826. He retired last year, and had gone to the Mediterranean to pass the winter. He was Honorary Physician to the Queen, and had received during his long career various decorations.

The Late Dr. Daubeny's Library.

The Magdalen College at Oxford has acquired, by the bequest of the late Dr. Daubeny, the whole of his very valuable library and scientific apparatus, and the sum of £1000 left as an endowment for the curator, to whose charge they shall be committed. It is expected that the College authorities will add a yearly sum from their own income to bring the remuneration up to an adequate amount, and to main-

tain the gift in a condition of efficiency for the advantage of the students of the College.

THE inaugural banquet of Dr. Carroll, the first medical Lord Mayor of Dublin, was held in the handsome ball-room of the Mansion House, on the evening of Tuesday, the 25th ult., and was honoured by the presence of his Excellency the Lord Lieutenant, Lord Strathnairn the Commander of the Forces in Ireland, and a majority of the distinguished persons officially connected with the Irish Government. The cordial feeling of the Lord Mayor towards his medical brethren was evinced by the liberality of his hospitality towards the profession. Almost all the physicians and surgeons of eminence in Dublin received invitations, and the Presidents and Vice-Presidents of the Colleges of Physicians and Surgeons occupied places on the *dais*. The toast of the Medical Profession was proposed in very feeling terms by the Lord Mayor, and was responded to by Dr. Churchill, the President of the King and Queen's College of Physicians in Ireland. The banquet was on the most generous scale, and both the *menu* and the attendance were pronounced to be markedly superior to those of former civic entertainments.

THE following classical invitation to a medical meeting was recently issued at New York. It calls to mind Swift's ludicrous latin doggrel:—

Apud in is almi des ire,
Mimis tres i ne ver re qui re.
Alo veri findit a gestis,
His miseri ne ver at restis.

The literal translation of which is:—

A puddin' is all my desire,
My mistress I never require.
All over I find it a jest is,
His misery never at rest is.

The *savants* of New York invite their friends as follows:—

"Doctores ! Ducum nex mundi nitu Panes: tritucum at ait. Expectu meta fumen tu te & eta beta pi. Super attento uno Dux, hamor clam pati ; sum parates, homine, ices, jam, etc. No Sideror Hoc. '*Festo resonan floas sole.*' Nov. Ebor Jan. 20."

Doctors ! Do come next Monday night to Panes. Try to come at eight. Expect to meet a few men to tea and eat a pit o' pie. Supper at ten to you know, ducks, ham or clam patty. Some (parates?) hominny, ices, jams, &c. No cider or hoc. Feast o' reason an' flow o' soul.

HARVEIAN SOCIETY OF LONDON.

FEBRUARY 6TH.

Mr. ERNEST HART, President, in the Chair.

DR. DRYSDALE exhibited a case of almost complete baldness from tinea decalvans.

Dr. FULLER then read a paper on the doses and actions of medicines.

He began his address by tracing the causes which have contributed to the prevalent distrust of medicine ; he then pointed out how this distrust has led to enormous and almost scandalous differences in the practices of different members of the profession, and concluded by asking the Society to take upon itself the arduous, but honourable work of investigating the action of medicines, and the doses in which they are tolerated in certain disorders, with the view of obtaining some trust-worthy therapeutical data.

The causes to which Dr. Fuller attributed the prevalent distrust in the efficacy of drugs, may all be resolved into the three following formulæ :—1st. The natural reaction from the overweening confidence in medicine, and from the wholesale and indiscriminate administration of drugs, which prevailed at the beginning of the present century. 2nd. The discovery that certain disorders if left to themselves in many instances tend to recovery. 3rd. The prevalence of extreme ignorance as to the doses in which each drug is tolerated by the system, and as to the dose in which it must be administered in order to obtain its curative effect.

From lack of knowledge on these last important particulars, some practitioners prescribe inadequate doses of a remedy, observe that it fails in modifying the course of the disease, and utterly ignoring their own want of judgment, blame the remedy, and learn to distrust it. Others in their search after precision in all that relates to the healing art, administer each remedy separately, and in a given dose in all cases, without regard to the strength or constitutional peculiarities of the patient, and without any reference to the state of the secretions, and finding that it often fails under these circumstances to effect the change they desire, conclude that it does not exercise a curative power. They insist that if a remedy possesses the power of modifying any disease, that power ought to be manifested whenever the remedy is administered, and refuse to admit in regard to medicine, what they are forced to acknowledge in respect to food, that "one man's meat is another man's poison." They forget that when the secretions are scanty and the internal organs congested, quinine even will fail to cure ague, and anxious, over-anxious, as to what they are pleased to term precision in their observations, they abstain from the administration of evacuants, which are essential even to the action of quinine. Thus in one way or another, while striving after accuracy, they arrive at conclusions the reverse of truth. Others, relying upon experiments on the lower animals, and ignoring or utterly regardless of the fact, that remedies act differently on different species of animals, conclude that some of our more valuable drugs do not deserve the reputation they have acquired, because, forsooth, the effects which have been observed to follow their administration in man are not manifested when they are given to dogs, cats, rabbits, and other animals. Others, again, of a still less practical turn of mind, are unwilling to admit the curative action of a remedy which has not an obvious effect on the pulse or secretions, or for which they cannot account on purely logical grounds. Inductive reasoning which has led to valuable results in chemistry and other sciences, is equally applicable, they think, to therapeutics, and in utter forgetfulness of the fact that inductive reasoning will not even serve to explain the action of quinine in curing ague, of jalap in stimulating the action of the bowels, or of chloroform in producing anæsthesia, refuse to admit the value of any remedy except on the ground they have chosen.

Thus, by one means or another, distrust has come to prevail, and discredit has been thrown on the curative action of drugs. Disease is left to take its natural course, and homœopathy is practised under the guise of scientific medicine. The public, who see by the reports of cases in our periodical literature, how little heed some men pay to medicine, are becoming indoctrinated with the belief that drugs are of no avail, and consistently betake themselves to the professed homœopath. For this belief, Dr. Fuller maintained that there are absolutely no grounds, and urged the Society to appoint a Committee for the purpose of investigating the subject of therapeutics and the actions of medicines. If, he said, it should prove on inquiry that drugs are of no avail in modifying the course of disease, let us, as honest men, avow our mistake, alter our practice, and admit that homœopaths have had just cause for their vilification of the legitimate practice of medicine ; but if, on the contrary, the labours of the Committee result in establishing the curative action of medicines when properly administered in doses, and in combinations suited to the exigencies of each case, the profession may fairly hope to obtain as the result of the investigation some trustworthy therapeutical data. The investigation must necessarily be coeval with the existence of the healing art, but the labours of the Committee if carefully conducted, would serve as a model to future inquirers ; the conclusions at which they arrive would be a nucleus to which other facts might be added from time to time, until information is obtained on the healing art, which would be indispensable to every practitioner, and, meanwhile, the Harveian Society would have the honour of inaugurating an inquiry, which would not have been unworthy of the Royal College of Physicians.

Mr. SEDGWICK thought that one of the great wants of the day was a Society through which we might obtain a better and more exact knowledge of the actions of medicines. Most inefficient doses of many drugs were prescribed, in consequence of the supposed danger of administering them in large doses. He was in the habit of giving digitalis in much larger doses

than was usually considered advisable, and had never seen any ill effects produced; and he considered there was no sufficient evidence of its accumulation in the system. In the mennorrhagia of women of relaxed habit, he found the tincture of digitalis especially useful in doses of from one to two drachms. An important point, on which much information might be gained, was the difference in the action of medicines when administered otherwise than by the stomach. Croton-oil seeds, for instance, in a case where the dust from them was accidentally inhaled, produced constipation; and it is well known that purgation does not necessarily follow the external application of the oil.

Dr. C. J. B. WILLIAMS could not forbear taking a retrospective glance to the time when he formerly appeared at this society, twenty-five years ago, in the companionship of Marshall Hall, Babington, Theophilus Thompson, and others; and he felt deeply moved, in looking round, as he missed the features of so many familiar friends. He congratulated the society on the success it had attained, and the important subjects which its committees had lately investigated, and on its courage in taking up a subject of such vast extent and importance. For his own part, he thought that not more was to be gained from a committee on this subject than from the social intercourse and conversation amongst medical men, to bring about and encourage which these societies were originated. Men in large and general practice have no time for committing to paper, or otherwise formally publishing, the information they are daily gaining, and so their individual experience dies out with them; the great knowledge and the masses of facts such men have often worked up being lost from the want of sufficient intercommunication amongst the members of the profession. There is no department of medicine more difficult, but at the same time there is none more important, than that of therapeutics; for where is the use or end of our science unless we can find some method of curing or alleviating disease? It is only by combined operation, by persevering investigation, and by minute attention to detail, that we are likely to overcome the difficulty of placing the treatment of disease on a satisfactory basis; and, in contradiction to this, it is humiliating to see how lightly the subject of treatment is commonly regarded, being usually dismissed in a few words at the end of the relation of a case, perhaps tediously elaborated in every other particular. It is too much the habit to decry new modes of treatment. Undeserved doubt is often thrown on the value of a drug from its careless or improper administration, from its being given in too large or too small a dose, or in an unfit combination, and from a variety of other circumstances. In a case of ague seen by Dr. Williams the patient had been taking quinine for some time in the form of pills, but without any effect. On examining the evacuations, some of the pills were seen in an unaltered condition. Quinine in solution was then prescribed, and a few doses effected the cure of the patient.

Dr. BROADBENT differed from Dr. Fuller in many points, and especially as to the probable value of the information likely to be collected by a committee. The amount of work to be done is enormous, and the time required would not be limited by the lifetime of one generation; it is work, too, requiring the most skilled powers of observation and the highest exercise of judgment. By applying to indiscriminate individuals for their experience and opinions, the committee would obtain a mass of materials of varied and questionable worth, and from which but very unsatisfactory conclusions could be derived, since the majority of men have never seen the natural course of a disease. This, the natural history of disease, is the first great problem to be ascertained: and it is now being worked at most zealously by men well fitted by aptitude and education for the task, and in charge of hospitals, where only the subject can be properly studied. Again, as to the modifying influences of different conditions of the system, how few men are really able to judge of these! Of the doses of medicines, we have already, in systematic treatises and scattered throughout the current literature, as trustworthy information as is likely to be collected by a committee; and we have a vast mass of information handed down to us by older writers, who believed firmly in their medicines and modes of treatment, and which is of equal value with any that might be indiscriminately collected at the present day. The remedies referred to as scattered throughout the country, and their value lost to the profession by their being limited to particular generations of men, were for the most part handed down by those who had never used anything else, and could therefore know nothing of the comparative value of any other method of treatment. A committee may be of use in making experiments with new remedies, and in trying the effects of various drugs in particular diseases, and an amount of information may thus be got together which will be useful to succeeding workers as a quarry from which they may obtain materials towards building up a true science of therapeutics. What we want at the present day is precise information. Our accurate observations will be to future medicine as the facts of chemistry are to the scientific system of which they are the foundation. The scepticism of the present age is but a healthy reaction from the contented and idle leaning on tradition which formerly prevailed; and the only way to get rid of it is to base our knowledge on careful induction from well-conducted experiments. As it is, remedies come into fashion, die out, and come in again. For instance, Dr. Glover, twenty-five years ago, introduced the bromides and wrote on them. Remedies come and go because men have no guide as to their real value except the opinion of the introducer. In trying remedies, it is necessary to have some kind of plan. His (Dr. Broadbent's) plan is to take substances chemically allied, such as arsenic, bismuth, antimony, and phosphorus, and try whether they are not therapeutically allied also. From his present results, Dr. Broadbent has reason to believe this is the case; that phosphorus, for example, is useful in the same class of cases that arsenic is known to be.

Dr. SUTTON said that the first thing necessary was to learn the natural course of disease. Extensive and valuable experiments have often been made with remedies, and certain results arrived at which have afterwards been completely upset by finding that the disease over which they were supposed to exert an influence got well just as soon without them. He had seen a very large number of cases of pleurisy with effusion recover without any medicine at all; so with pneumonia; in cholera, too, under the most opposite plans of treatment, a certain number of cases recover. Our duty is to ascertain, as far as we can, what class of cases is likely to get well of themselves and what is not. When in charge of the Cholera Hospital, experimenters frequently asked to be permitted to try particular remedies. He told them that he would divide the patients admitted into two classes, those who were, according to his experience, evidently likely to get well if left alone, and those who were not. They might deal with either or both; but the results would necessarily be very different in the two classes, and not comparable. This was a frequent source of fallacy.

Dr. DRYSDALE thought Dr. Fuller used the word empiricism in a wrong sense, as in most cases we know beforehand the action which drugs are likely to produce, and so we really proceed by induction. Empiricism consists in using drugs, such as quinine, iodide of potassium, &c., of which we do not know the mode of action on the organs. It is almost impossible to get at results by the empirical method; and it is only by mere chance that we have discovered such facts as that quinine will cure ague; colchicum, gout; arsenic, certain forms of skin disease, &c.; and we know no reason why these remedies are useful in these diseases. The Committee should limit themselves to the discussion of points on which evidence was already accumulated; experiments can only be properly carried out in hospitals.

After observations by Mr. ISAAC BROWN and Dr. KIDD,

Mr. BENSON BAKER said that he found there was a great difference in the action of drugs upon people living in the country and upon those living in town; it was also important to bear in mind the condition of the patient at the time of administration, and the circumstances surrounding him.

Dr. SILVER stated that considerable advances were being made of late years in the science of therapeutics, especially in Germany, where some important experiments were being made as to the chemical action of drugs on the blood and other tissues. It was found that arsenic had a preservative action on the living tissues as on the dead; that it prevented oxidation, and diminished the excretion of urea. Clinical experience was very valuable; but chemical investigation he believed to be of still more value. The different forms and combinations of medicines should be sought out, and their actions investigated. Of new remedies, there were scores unknown to us in daily use in America; and some of our own men—notably Sir James Simpson—were in the habit of using many drugs rarely heard of beyond their own sphere. But, with regard to nearly all of these new remedies, they are alleged to have so many and such diverse actions, that we become sceptical as to their having any action at all. The action of some secret remedies was worth taking up, some, such as Warburg's fever tincture, have established a real and well founded reputation.

Dr. MEREDYTH put more trust in ascertaining the physiolo-

gical action of medicines, and thought we must have a proper classification to furnish a scientific basis for our investigations.

Dr. BEHREND thought that one cause of the present scepticism was the enormous adulteration of drugs practised, making it commonly doubtful whether a patient was really taking what we prescribed. A patient of his took extract of belladonna for some time without any effect; but, on getting his medicine from a fresh druggist, a few doses sufficed to effect a cure. The Committee should endeavour to get legislative action on this subject.

Dr. DANIEL suggested that different remedies should be chosen for discussion on different evenings.

Dr. CAMPS had found a great difference in the action of drugs obtained from different places. Physiology and chemistry aid us in arriving at approximate truth; but we cannot expect to get exact results with such a complex machine as the human body.

The debate was here prolonged, at the wish of the Society, beyond the usual hour.

Dr. HANDFIELD JONES thought we had already pretty well ascertained the natural history of some diseases, such as the exanthemata; of others we have great difficulty in tracing the history, as we know not when they begin or end. He had prognosticated an attack of rheumatism from the smell of the patient, and the flying symptoms one month before the actual attack occurred. Of many diseases, we must almost despair of obtaining the natural history; and it seems preposterous to wait for this before attempting to relieve our suffering patients, when a very short observation will show us whether a remedy is likely to do good or to minister to our patient's comfort. One duty of a Committee would be to find out whether acute disease can be shortened in duration. Dr. Jones believes that it can; that low diet and lowering measures often cut short an attack. For example, dysentery may most decidedly be shortened by leeches and ipecacuanha. What are diseases? and what is the treatment of a disease? These questions we cannot answer; one patient with delirium tremens may be cured by a purge, another by opium, another by tartar emetic. For our indications as to treatment, we must look to the individual patient rather than to the disease; we must examine all his tissues and organs, and find out how they act and secrete, and how they are influenced by various agencies. We shall then be able to apply our therapeutic knowledge to put him in a better position to overcome his disease.

Mr. CURGENVEN thought that one cause of the present scepticism was the cessation of the apprenticeship system, so that many men now went into practice without any knowledge of the appearance of drugs or of their incompatibilities, &c.

Dr. POLLOCK believed that the Committee, if it took too wide a programme, would merely get together a heterogeneous mass of opinions, which would be of little value. What we require is, to watch and compare the application of remedies in similar sets of phenomena; and this investigation can only be carried on by very careful observers in large hospitals. In order to ascertain the real influence of drugs, they must be given singly; and he found that even in actual practice fewer combinations were used, and even fewer drugs given, as experience was gained and a man became older. He would rather propose that the Committee should investigate the effects of remedies on the healthy subject.

The PRESIDENT congratulated the Society on the presence of so many distinguished members and visitors, and on the part they had taken in this interesting debate. He did not take so wide a view of the duties of the proposed Committee as some of the speakers, who appeared to think it was intended to take up the whole subject of the treatment of disease. It would be left to the committee to select a small portion of the subject at a time; perhaps the action of one drug, or the natural history of one disease, and to bring up special reports from time to time for discussion in the Society. If the investigations were properly limited, great good might result from them. There are many points to be cleared up with regard to some of the most commonly used drugs; for instance, as to the proper doses of iodide of potassium. He gave instances of great varieties of opinion on this subject. Summing up the opinions expressed during the evening, he discussed briefly the causes of the existing scepticism, which he believed to be a healthy revolt against the mass of heterogeneous traditions with which medicine is loaded; and expressed the hope that the Committee might assist to clear a small patch of ground, if it could not begin to build.

Dr. FULLER, in reply, had no intention of proposing a Committee to take up the whole subject at once, but that it should be left to the Committee to select certain points and to investigate them thoroughly. Most valuable information might be obtained from country practitioners, many of whom were celebrated throughout a whole county for their treatment of some particular disease, and it would be surely desirable to ascertain their traditions, experience, and methods. The combination of medicines is often most serviceable, and may often increase the activity of any one of those combined; but in experiments it is certainly desirable to confine oneself to single drugs. He concluded by moving the appointment of a committee, to make a preliminary report to the Society at as early a date as convenient, the committee to consist of the following gentlemen: —Drs. Broadbent, Tilbury Fox, Fuller, Hare, Hickman, Handfield Jones, Morton, Pollock, Sanderson, Sieveking, Messrs. Ernest Hart, Curgenven, and Sedgwick, with power to add to their number.

This was carried unanimously.

Correspondence.

ON THE REMUNERATION OF MEDICAL OFFICERS TO BENEFIT SOCIETIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As there is a great deal of agitation just now with regard to the payment of medical men holding club appointments, I trust the following suggestions may not be out of place. One cannot help thinking how great a pity it is that all club-surgeons (in towns at any rate) cannot by some means or other come to a determination to seek for more payment for their services, all agreeing to be faithful to each other, and to resign in a body if their just demands are not satisfied; at the same time the neighbouring medical men should promise to stand by them and uphold the honour of the profession at large, by refusing to have anything to do with the clubs in the event of the old surgeons being turned off, and the clubs offered to any of them because the former asked for more money for their services. Now suppose a club paid a surgeon after the rate of five shillings for each member's attendance and medicine a-year, I think even then the sum would be much too small to meet the extra work demanded of the club doctor—by extra work, I mean more particularly early morning, evening, and night visits. I believe all such visits should be paid for in addition (say out of the general funds of the club, or by individual members as agreed upon amongst themselves) to the standing fee for general attendance, for one must bear in mind that after a surgeon has accepted a club contract, at the present rate of payment, he is entirely at the mercy of any member thereof who may fancy, because the doctor is paid for his work, that he can summon him to his house at any hour of the night, let the cause be ever so trifling; and should the surgeon remonstrate at being thus unnecessarily fetched out, he generally meets with this reply—"Well, sir, you know, being in a club, I thought I might as well have you as not." Now had such an individual to pay half-a-crown for such a visit, he would have thought twice before he sent for the doctor, perhaps tried the effect of a few home remedies, and waited until the morning before he applied for aid, unless necessity compelled him to call in such aid sooner. If one can obtain the doctor gratis in the night, then have him! If it cost one anything, wait and see how things turn out! What the club-surgeon wants, is protection from a few members who never consider his time, and who never care how much extra trouble they give him; and who for the merest trifle will have him to see them, instead of putting themselves to the inconvenience of calling upon him at the surgery. If asked, why did you not come to me? the surgeon has cast in his teeth,—"Are you not paid for your work?" Yes, certainly, after a fashion, but the sum is so absurdly small in proportion to the work done, that you would never find the members composing such a benefit society doing their work, whatever it might be, at such a ratio of payment, not they, forsooth! But still they are unreasonable enough to expect their surgeon to do so, and I am sorry to say there are many to be found who still will work for a small fee, either because they are content with it—or, to be more charitable, I suppose necessity compels them to do so; for two reasons—1st, in many cases to make both ends meet, for if they gave up a club, they must part with some of their private patients; 2nd, they know but too well if they asked for advance of salary they would be dismissed, and that other medical men would only be too glad to

come forward, hat in hand, to solicit the honour, &c., to be elected club-surgeon on the old terms, or may be after a lower rate of payment; a humiliating and melancholy fact, but no less a true one for contemplation and reflection by the whole of the medical profession at large. Unity is strength we all know, and if club-surgeons would only decline in a body to have anything more to do with clubs on the old terms, and obtain the support and sanction of their professional brethren, which no honourable member of the profession would refuse, I feel certain they would obtain a fair remuneration for their services, and one the working-class could well afford to give. I think, in addition to the retaining fee for general attendance and medicines, something ought to be paid for each *first visit* (nothing for the subsequent ones of the same illness)—according to the time the surgeon has to pay the first visit. We will divide such visits into *ordinary*, *special*, and *night* visits. By an ordinary one is meant a visit paid after the message requesting it, and providing that message was left at the surgeon's residence not later than ten o'clock in the morning. By a special visit is meant one paid in consequence of the message not being left at the surgeon's until after 10 A.M., and not later than 5 P.M., thus requiring frequently the medical officer to retrace his steps to see a club-patient after he comes home from his daily rounds, because such patient, to suit his own convenience, did not let the surgeon know he was wanted till mid-day, waiting perhaps for a neighbour who might be going through the village where the doctor lived, to call and say Mr. So and So was ill, in many cases "very bad," and the doctor must come directly, instead of sending a messenger on purpose in time to be at the surgery before the doctor left for his daily work. By a night-visit is meant one paid in answer to a message left at the surgery at or after five in the evening, and before ten next morning, requiring immediate attention. Of course, I am only speaking now of first visits by request of patients, not a visit paid late in the day, to suit the surgeon's own convenience. If necessary to see a patient twice daily, the second visit to be half-a-crown extra, or if patient alters for the worse, and it is necessary for such a one to be seen in the night, then certainly five shillings is not too much for the surgeon's night-visit. If something in addition to the ordinary fee for general attendance and medicines had to be paid for each first visit, as stated above, it would compel members to be more cautious how (to save themselves one iota of trouble) they indiscriminately send for the medical officer just when they pleased, whether there was occasion for immediate attention or not. If club members had to pay for their first visit they would frequently find they could walk to the doctor to have a wound dressed, or obtain advice or medicines, as well as trouble him to come to them; in fact, medical officers to benefit societies would be protected from the whims and fancies of certain members thereof, who fancy, because they have paid their half-crown, often less, seldom more, for their attendance for the year, that they are entitled to fetch the doctor at any moment for every little ailment they may think requires attention. The surgeon to a club is to the members little better than a flunky, and there are not a few members who thus look upon him, and is it to be wondered at when medical men take medical contracts at the present ruinous and degrading rate of payments for *professional* services? I believe the following tariff of charges to be a fair one:—

	s.	d.
For general attendance and medicines for each member per annum	5	0
First ordinary visit, including signing a certificate to go on the club and another to go off	1	0
First special visit and certificate, &c.	2	6
First night-visit and certificate, &c.	5	0

Patients who, to suit their own convenience, will call at the surgery after consultation hours to pay one shilling; teeth extracted, one shilling during surgery hours, eighteenpence afterwards; passing a catheter, half-a-crown; bandaging broken ribs, ten shillings; treating fractured collar-bone, one pound; reducing dislocation of fingers, ten shillings; amputating a finger or toe, one pound. The capital operations to be charged for in accordance with the scale of payment allowed by the Poor-law Board to their Medical Officers. Bottles, bandages, splints, leeches, and cod-liver oil, to be found by patients themselves. With regard to examination by the surgeon, and the report as to state of health of candidate for admission, as member of a benefit society, we are fully aware, in the majority of cases, that such report is given gratis, it ought not be; a fee of certainly no less than half-a-crown ought to be charged in all cases, if made at the, and during, surgery hours; if after, or at candidate's house, five shillings is none too much for making such examination and writing the requisite certificate. If clubs paid their surgeons after the above rate, the members would find themselves much better off than they now are in the long run, and there would be much more friendly feeling existing between doctor and patient than at the present time, for it stands to sense and reason, that as things now are, the doctor thinks how little he need do for his money, the patient how much he can get for his; a very satisfactory state of affairs for the patient, as club patients frequently think that the doctor does not come often enough to see them, and, it is a well-known fact, they require more attention than a private patient. The above tariff of club-payments is certainly a good one, but I fancy medical men would do better for themselves, and that the patient would experience more satisfaction if contracts were made, not in the lump as above, but after the rate of so much for each visit, according to time of such visit, and have all medicines found by a chemist (if a chemist could be found to contract for medicine for the year); pay a medical man for what he really does, whether it be much or little, not get him to take so much at the risk of having but little to do as the rule now is. Suppose a club agreed to pay their surgeon 1s. per head per annum as a retaining fee for general advice, and then allow him 1s. for each ordinary visit; 2s. 6d. special; and 5s. night, ditto. The rules with regard to attendance at the surgery and operations to be charged for as stated above. Let club-surgeons remember, if they make any alteration with regard to payments, they may as well have a good and just scale of remuneration, as be content with the rise of 1s., or more, as the case may be, in addition to their present pay per head. Let club-surgeons bear in mind, and club-members too, that "the labourer is worthy of his hire."—I am, sir, yours, &c.,

HENRY W. WILLIAMS, M.D.

168, Fulham-road, S.W.

THE BRITISH LYING-IN HOSPITAL AND THE LADIES' MEDICAL COLLEGE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am obliged to trouble you with a few facts in relation to your editorial comments at page 195.

1. The "merits or demerits of the Female Medical College" were not introduced by me, and I have no wish to follow further what is, as you rightly say, irrelevant to the matters asserted by Dr. Eastlake.

2. The fact, that having examined the prospectuses and reports, you are "by no means disposed to condemn the principle upon which the college was founded" is a very mild expression for the conclusion to which all honourable men in the profession will come on due inquiry, and to which a very large number have already come, and upon which a considerable number have practically acted, by entering their daughters and relatives as students at the college. I find that the last two entries were sisters of a well-known medical practitioner in Ireland, and I have by this very post received a letter from him, containing warm expressions of thanks for my share in organizing the arrangements of which those ladies have availed themselves.

3. "Sneering allusions to man-midwives" have not, so far as I know, been circulated by the Female Medical Society or any of its officers. If otherwise, I shall thank you to point out the instances.

I have myself used the term "man-midwife," but not "sneeringly." I prefer Saxon to bastard French, and do not know that the English language provides those gentlemen with any other designation. I need not remind your readers that the word "man-midwife" has but recently been superseded upon the brass-plate by the euphuistic term "accoucheur," and that many eminent obstetricians now living, have gloried in the designation "physician man-midwife." The *Athenæum* of September 28th, 1867, in a long and interesting article upon this subject, which all medical men should read, selects the term "man-midwifery;" and Dr. John Brown, Lord Rector's Assessor to the University of Edinburgh, at page 26 of the introduction to his classical work "Horæ Subsecivæ Lock and Sydenham" (1866 edition), also selects this term, and uses it with a freedom more open to objection from "people of over-nice minds but nasty ideas" than any use to which I have ever put this homely and significant bit of saxon. The passage is worth quoting. He says:—

"There is one subject which may seem an odd one for a miscellaneous book like this, but one in which I have long felt a deep and deepening concern. To be brief and plain I

refer to 'man-midwifery,' in all its relations, professional, social, statistical, and moral. I have no space now to go into these fully. I may, if some one better able does not speak out, on some future occasion, try to make it plain, from reason and experience, that the management by accoucheurs, as they are called, of natural labour, has been a greater evil than a good, and that we have little to thank the grand monarque, for, in this, as in many other things, when, to conceal the shame of the gentle La Vallière, he sent for M. Chison instead of the customary *sage-femme*.

"Any husband or wife, any father or mother, who will look at this matter plainly, may see what an inlet there is here to possible mischief, to certain unseemliness, and worse. Nature tells us, with her own voice, what is fitting in these cases, and nothing but the omnipotence of custom, or the urgent cry of peril, terror, and agony, what Luther calls *miserrima miseria*, would make her ask for the presence of a man on such an occasion, when she hides herself and is in travail. And, as in all such cases, the evil reacts on the men as a special class, and on the profession itself.

"It is not of grave moral delinquencies I speak, and the higher crimes in this region; it is of affront to nature, and of the revenge which she always takes on both parties who actively or passively disobey her. Some of my best and most valued friends are honoured members of this branch, but I believe all the real good they can do, and the real evils they can prevent in such cases would be attained if, instead of attending—to their own ludicrous loss of time, health, sleep, and temper, some two hundred cases of delivery every year, the immense majority of which are natural and require no interference, but have, nevertheless, wasted not a little of their life, their patience, and their understanding—they had, as I would always have them do, and as any well-educated resolute doctor of medicine ought to be able to do, confined themselves to giving their advice and assistance to the midwife when she needed it.

"I know much may be said against this—ignorance of midwives, dreadful effects of this, &c., but to all this I answer, take pains to educate carefully and to pay well, and treat well these women, and you may safely regulate ulterior means by the ordinary general laws of surgical and medical therapeutics. Thus, instead of a man in general practice, and a man, it may be, with an area of forty miles for his beat, sitting for hours at the bedside of a healthy woman, his other patients meanwhile doing the best or the worst they can, and it may be, as not unfrequently happens, two or more labours going on at once; and instead of a timid, ignorant, trusting woman, to whom her Maker has given enough of sorrow, and of whom Shakespeare's *Constance* is the type, when she says, 'I am sick and capable of fears, I am full of fears, subject to fears; I am a woman, and therefore naturally born to fears'—being in this hour of her agony and apprehension, subjected to the artificial misery of fearing the doctor may be too late, she might have the absolute security and womanly hand and heart of one of her own sex.

"This subject might be argued upon statistical grounds and others, but I peril it chiefly on the whole system being unnatural. Therefore, for the sake of those who have borne and carried us, and whom we bind ourselves to love and cherish, to comfort and honour, and who suffer so much that is inevitable from the primal curse, for its own sake, let the profession look into this entire subject in all its bearings, honestly, fearlessly, and at once. Child-bearing is a process of health, the exceptions are few indeed, and would, I believe, be fewer if we doctors would let well alone."

Having disclaimed for the Female Medical Society—my medical colleagues and myself—all disrespectful allusions to the Medical Profession, I yet hold that it has not hitherto done its duty in the education of midwives, and that such conduct as that lately exhibited by the *British Medical Journal* and the *Medical Times* must be disowned before it can come into Court with clean hands as a complainant.

I have always held that all barriers excluding women from any branch of medical practice, or indeed from any other field of labour, should be removed, but that it is actually desirable and necessary for the public welfare that proper facilities should be organised for educating, examining, and licensing midwives, and that the best possible teaching in the science of obstetrics and all the accessory branches of medicine should be made accessible to educated women in a school apart from male students. *I have never proposed to exclude men from the practice of midwifery, but only to prevent men from excluding women*, as practically they have for a long time succeeded in doing by preventing them from being properly educated.

The Female Medical Society has never "catered to the petty prejudices of strong-minded women." It has, in fact, incurred a spiteful enmity in certain quarters by its persistent refusal to commit its organization to extreme or impracticable views (*vide* Social Science, Sep. 20, 1867). "The suspicion with which the operations of this institution has been regarded by the profession" is not due to any action on the part of its friends or promoters; it is in fact due solely to the mischievous activity and silly notions of such medical persons as those who have exhibited themselves in the recent conduct of the *British Medical Journal* and *Medical Times*.

Of course the medical profession would not countenance these miserable mischief-makers, but so few of us know *in propria personâ*, the creatures who pull the wires of this kind of machinery, that we unconsciously allow our minds to be prejudiced or misled by what appears in anonymous print from men to whose opinions, if otherwise expressed, we should pay no attention whatever; and nothing, sir, could illustrate this better than the fact that a professional man of your experience has just been duped by these two precious journals.

4. As you point out, "that which Dr. Edmunds designates an 'impudent falsehood,' is not only specifically stated, but vehemently reiterated by Dr. Eastlake." As Dr. Eastlake's attack upon the hospital, and upon the two defenceless women has recoiled upon himself, I have no wish to gibbet his conduct in further detail in your pages. I will merely state that I never saw Dr. Eastlake before I subscribed to the hospital, and had no sort of personal feeling against him, and no wish that he should be disturbed in his post as physician. He has in fact brought all this trouble and disgrace upon himself by a series of actions, every one of which has been "not only a crime but a blunder."

If any readers are not satisfied as to whether the veracity is on the side of the Board of Management or of Dr. Eastlake, I shall be happy to send them a full report of the special general meeting from the London *Mirror* of the 22nd inst., together with printed copies of other documents As to the charge of "packing," the *fact* that the resolutions were carried *unanimously* at the general meeting of governors shows that we had no necessity for such an expedient. Dr. Eastlake did try to do it at the last moment, but was defeated in the attempt.—I have the honour to be, sir, your obedient servant,

JAMES EDMUNDS, M.D.

4, Fitzroy-square, London, W.
Feb. 27th, 1868.

P.S.—I have just been told by a mutual friend fresh from Wimpole-street, that the Editor of the *British Medical Journal* not knowing how to wind up this matter, has hit upon the expedient of getting up a requisition for a special general meeting of the metropolitan branch, ostensibly "to take into consideration the treatment which Dr. Eastlake has received at the hands of the Governors of the British Lying-in Hospital," but really to rid himself of his embarrassment. In order, as I suppose, to keep up the unity of the plot this forthcoming meeting is put forward in the journal as a reason for continuing to suppress my reply as a governor of the hospital and member of its board of management, and I infer that the knowing editor in his superior wisdom thinks that the objects of that meeting could not be accomplished if both sides of the question were placed before the members of the association.

I hope that the reporters of the general press will not be admitted, as then, if the meeting makes the association ridiculous the reports can be quietly burked and no harm will come of it. If, however, as I am told, this is a first attempt to erect the British Medical Association into a trade's union combination for intervening between medical men and their employers, I regret that Dr. Eastlake should have been selected as the type of a medical martyr, and that a hasty meeting of the profession should be exposed to the risk of committing itself to the support of an attack to which they have not heard the reply, and upon which it seems bad generalship to base the consideration of a principle so wide and important. Attached to the "requisition" are, of course, several names which we all respect and hope to continue to respect, but those gentlemen do not know that their signatures are followed by that of another who, as one of the valiant cohort with which Dr. Eastlake attempted to pack the Governors' special general meeting, tried to force his way in on the assertion that he had paid his governorship qualification into the hospital account at the bank "last week." With much regret, and some hesitation, the scrutineer at the door, after much discussion, directed the police guard to resist his entry by force, and this medical gen

tlemen with others walked up and down the outer hall arranging to "hound that fellow Edmunds out of the profession," an object which a "midwife" who stood by to identify the persons of the governors, told them would be the greatest kindness they could do to him if *they* were fair representatives of it. The secretary of the hospital has since carefully examined the account at the bank, and finds that this medical gentleman (save the mark) had made no payment whatever. I deeply regret to have to make this statement, but to shrink from it would be to neglect my duty to the profession, and I am prepared to point out the name if necessary.

I shall be thankful for the support and sympathy, or advice and criticism of my professional brethren in regard to the work I am trying to help on.

The reference in my last letter to "the *British Medical Journal*, Vol. II., 1864," should have been 1865, Vol. II., pages 434, 463, and 510. J. E.

STAMPING OUT SMALL-POX.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The subject matter of this communication in its bearing upon a recent pamphlet[1], from the pen of Sir James Simpson, may render necessary an apology from so obscure an individual as myself, for what might otherwise be deemed an unwarrantable obtrusion; but, as the remarks I have to offer stand associated with a due regard for the high scientific and professional position of the writer of the pamphlet, I trust they will not be considered either impertinent or irrelevant. It is simply with the postulate of the argument upon which the practical details are based, that I have to do. In a sanitary point of view, the entire paper must commend itself to the judgment of the profession at large.

The article to which I refer is headed, "Proposal to Stamp out Small-pox," &c., and in it there occurs the following paragraph:—

"Let it be premised that small-pox is like scarlet fever, measles, and whooping-cough—only a species of disease which, as a general law, attacks once in a lifetime, and is only propagated from an infected individual to a susceptible individual by a specific poison generated in the course of the malady, and transmitted from the affected to the healthy—first by the near approach of the one to the other, &c. We would no more expect this known species of disease or poison to originate *de novo* at the present day, under any combination of circumstances, than we would expect a known species of animal or plant—as a dog, or a hawthorn—to spring up *de novo*, and without antecedent parentage."

Again, "The public mind has, during the last two or three years, become familiarised with the idea of '*stamping out*' a disease, in the instance of rinderpest—a malady apparently spreading in this country, only as small-pox does by contagion; and every one well knows the perfect success with which this affection has been lately stamped out in England, while it has also, by due care, been prevented spreading to Ireland, and the Isle of Man. I believe the same principle of stamping out could be as successfully applied to the extirpation of small-pox among us, as it has been applied to the extirpation of rinderpest."

The precise meaning of the above is made perfectly clear by the following, in the concluding paragraph:—

"My observations in the present communication refer especially to the stamping out of small-pox, for I believe it is the malady whose extirpation could thus most easily be effected. But the same principles apply, and will, I believe, be applied betimes to the analogous contagious diseases, when the science of public health is more advanced, for the study of it is yet in its infancy. Scarlatina and measles will become greatly reduced, if not extirpated, by an observance of similar rules."

Now, assuming that small-pox must be ranked with the formidable array of epidemic diseases, I think it will be pretty generally conceded, that, recurring as these do, respectively by simultaneous visitations, in districts widely separated from each other—it may be after long intervals of suspension—and without any appreciable premonition, they must be influenced in this their *primary* form, by mysterious laws, which no human foresight can altogether evade; and to promulgate a theory (under a popular designation), which ignores these laws, by a presumption that human resources may be made available for the extinction, *toto cælo*, of any one of this class of diseases, appears to be indicative of a mode of thinking in relation to the economy of the moral governor of the world, which I imagine the worthy baronet would be among the foremost to repudiate.

How far the theory to which I have ventured to take exception may be applicable to the same class of diseases, in their *secondary* or contagious characters, is a totally different question; inasmuch as we are happily provided with hygienic means of the kind suggested by Sir James for *limiting* their operation. J. BIRCHENALL, M.R.C.S.

Macclesfield.

ANOTHER IMPOSTOR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Since writing last on the history of the man found drowned at Abridge, in Essex, I have been confirmed in my suspicions that there were two impostors adopting the same trick.

I might almost exclaim with King Richard—

"Methinks there be six Richmonds in the field,
Five I have slain to-day instead of him."

It is quite certain that the man who was drowned in Essex called on some medical gentlemen in the neighbourhood and represented to them that he was "Dr. Scholfield, of Pickering." He told the oft-repeated tale which had been used by Roscoe; and his age, mode of address, height, and general appearance, corresponded with the "original author of the imposture," Roscoe of Bolton.

But my letter published in your columns has revealed the fact that there is another person telling the same story and adopting the same means of obtaining money under false pretences.

I am sure that the real Dr. Scholfield, of Pickering, who is a highly respectable man, still in practice there, would be glad to know that this infamous mis-use of his name had been stopped and punished. I should gladly co-operate with any one who would assist in bringing the fellow-swindler No. 2 to justice. It seems that he is haunting London at present, for he called upon Dr. Cheadle, of Cumberland-gate, on Friday evening last.—I am, sir, yours obediently,

BAXTER LANGLEY.

50, Lincoln's-inn-Fields, W.C.
March 3rd, 1868.

Medical News.

ON Tuesday last, H.R.H. the Princess Christian made a private visit to the Hospital for Women, Soho-square, to inquire after one of her Royal Hignesses' servants, who is an inmate of that institution. Her Royal Highness visited some of the wards, and expressed her gratification at the general arrangement of the hospital, and the appearance of comfort which the wards presented.

THE Military Secretary, India Office, presents his compliments to the Editor of THE MEDICAL PRESS AND CIRCULAR, and begs to enclose a list of the candidates for her Majesty's Indian Medical Service who were successful at the competitive examination at Chelsea in August last, and who have undergone a course of instruction at the Army Medical School, together with the names of places where they have studied, and the total number of marks obtained at the examinations at Chelsea and at Netley:—A. S. Lethbridge, Aberdeen and England, 5451; A. Stephen, Aberdeen, 5386; J. J. Rathon, Ireland, 5305; J. H. Newman, Ireland, 4984; H. Johnstone, Aberdeen, 4767; W. R. Gordon, Aberdeen, 4436; J. Davidson, Aberdeen, 4388; A. S. Jayakar, London, 4291; J. F. Keith, Aberdeen, 3972; E. A. Trimnell, England, 3829; C. A. Harvey, Edinburgh and Ireland, 3543; W. Hanks, London, 3339.

THE Dublin Obstetrical Society will hold their sixth meeting for the session, in the Rotundo, on Saturday next, when the following communications will be made:—1. T. E. Beatty—Case of Fibro-cystic Tumour of the Vagina. 2. J. A. Byrne—Case of Retained Menses. 3. H. S. Halahan—On Anomalies in the Mechanism of Parturition. 4. J. Guinness Beatty—On Rigid Perineum. 5. R. W. Harley—Case of Gonorrhœal Rheumatism after Parturition.

WE hear that the little boy Abbott, who was blinded at the Clerkenwell explosion, has recovered his sight.

Dr. LETHEBY'S SECOND LECTURE ON FOOD.

COMPARATIVE DIGESTIBILITY OF FOODS—FUNCTIONS OF DIFFERENT FOODS.

(Continued from page 219.)

And with regard to the use of *fermented liquors*, there is the same universal indication of their serving a profound physiological purpose, and supplying a common want. It is no argument that, because these things have been abused they serve no purpose in man's economy. On the contrary, the fact of their use in all time, and that no saccharine liquid, or juice of ripe fruit, can be exposed to the air without spontaneous and almost immediate fermentation, are striking evidences of a useful purpose. They may not enter into composition of tissues, but they may stimulate the energies of the living frame, and rouse them into increased activity. It is not merely the brick-work and marble, so to speak, of the human body, nor yet the concrete movements of the machine, that have to be sustained, for there are rarer forms of matter, and higher manifestations of force, concerned in man's existence; and his resort to such beverages as these, may be for something more than the nourishment of the system, or even the mere raising of his spirit above the common concerns of this work-o-day world.

That *alcohol* stimulates the action of the nervous system there is no doubt, and it is equally certain that it increases the respiratory changes. Dr. Edward Smith is of opinion that it also lessens the action of the muscles, which are subject to volition, and increases, in a certain degree, the action of those which are independent of it, as the heart and respiratory muscles. He finds, too, that it diminishes the functions of the skin, and by thus lessening the waste of animal heat, it has a conservative tendency. The effects of alcohol are, however, much modified by the substances with which it is associated in different alcoholic liquids—*beers* and *ale*, for example, act on the respiratory functions by reason of the saccharine and nitrogenous matters they contain; *wine* also, as well as *cider* and *perry*, have a similar action, and in proportion to their saccharine and acid constituents; *brandy* and *gin* lessen the respiratory changes, and the latter acts on the kidneys by reason of the volatile oil it contains; *whiskey* is uncertain in its effect on the lungs; and *rum*, like *beer* and *ale*, is a true restorative, as it sustains and increases the vital powers; and he says that the old-fashioned combination of *rum* and *milk* is the most powerful restorative with which he is acquainted.

Liebig is of opinion that alcohol is burnt or oxydised in the system, and is therefore a calorific agent; but the researches of Lallemand, Perrin, and Duray, as well as those of Dr. Edward Smith, have demonstrated that a large portion of it passes through the system unchanged, and appears in the breath and perspiration, as well as in the urine. They, therefore, conclude that alcohol is not a food, but is a mere excitor of the nervous centres. On the other hand, Dr. Thudicum, in a rather large experiment on the students of his class (33 in number), found that of the 4000 grammes of alcohol in the 44 bottles of wine, which they drank at one sitting, only 10 grammes appeared in the urine; and assuming that about 10 grammes more were exhaled by the breath and skin, he concluded that only 0·5 per cent. of the alcohol escaped unchanged. He therefore believes that alcohol is oxydised in the body, and is a true food.

But besides this, the inquiries of Poiseuille have shown that it is a physical as well as a chemical and physiological agent, for it hinders the flow of liquids in narrow tubes, and may act in the same way on the movements of the blood in the capillary vessels. He found, for example, that when the flow of a certain quantity of water through a small tube occupied 575·8 minutes, and of the serum of blood 1048·5 minutes, the flow of the same quantity of Madeira wine under the same circumstances was 1138 minutes, of sparkling Sillery 1463, and of Jamaica rum 1832. Its functions, therefore, are manifestly of a complicated nature: in fact the whole subject is remarkably obscure, and requires the light of science to illuminate it. As in the case of tea and its allies, ages of empiricism are waiting for a philosophical interpretation.

Lastly, as to the functions of *condiments*, as *peppers*, *mustard*, *spices*, &c. They are merely stimulants of the digestive organs—promoting the flow of the saliva, the gastric juice, and other intestinal secretions; and increasing the paristaltic movements of the viscera. They thus aid in the processes of digestion; and by giving flavour

to the food, they wet the appetite, and so increase the relish for it—indifferent food is thus made palateable, and its digestion accelerated.

And now, in conclusion, we may safely inquire, as a supplementary question to the functions of food, what are the mechanical and thermotic powers, as well as the fattening capabilities of various articles of diet?

Dr. Frankland has made some very careful determinations of the calorific values of different substances used as food; and remembering that every pound of water raised one degree of Fahrenheit represents a mechanical force of 772 lbs. lifted a foot high, it is easy to calculate the working energy of any substance from its thermotic power when burnt in oxygen, or when less perfectly consumed in the animal body. Arranging the results under these two heads, we shall find that the energies of different articles of diet may be thus expressed:—

ACTUAL ENERGY OF TEN GRAINS OF THE MATERIAL, IN ITS NATURAL CONDITION, WHEN COMPLETELY BURNT IN OXYGEN, AND WHEN OXYDISED INTO CARBONIC ACID, WATER, AND UREA, IN THE ANIMAL BODY.

	Per cent. of water in material.	Lbs. lifted one foot high. When burnt in oxygen.	When oxydised in the body.
Butter	15	14357	14357
Cheshire cheese	24	9187	8613
Oatmeal	15	7913	7769
Wheat flour	15	7788	7591
Pea-meal	15	7778	7456
Arrow-root	18	7731	7731
Ground rice	13	7535	7424
Yelk of egg	47	6761	6532
Lump sugar	19	6616	6616
Grape sugar	20	6476	6476
Entire egg	62	4708	4507
Bread crumb	44	4409	4246
Ham	54	3915	3317
Mackerel	71	3537	3187
Lean beef	71	3098	2818
Lean veal	71	2594	2314
Guiness' stout	88	2123	2123
Potatoes	73	2002	1969
Whiting	80	1787	1563
Bass' ale	88	1530	1530
White of egg	86	1325	1138
Milk	87	1306	1241
Carrots	86	1040	1026
Cabbage	89	858	830

It will be understood, of course, that to obtain these results in the animal body the materials must be completely absorbed, and fully oxydised into carbonic acid, urea, &c.

Estimated in this manner it may be said that a daily subsistence diet of two ounces of dry nitrogenous food, and 13·2 ounces of dry carbonaceous, calculated as starch; and a daily working diet of six ounces of dry nitrogenous matter, and twenty-six ounces of dry carbonaceous, have the following mechanical energies:—

	Lbs. lifted one foot high. When burnt in oxygen.	When oxydised in the body.
Subsistence diet ...	6,319,783	... 6,307,078
Working diet ...	13,349,405	... 13,311,290

But the actual working power of the human body does not approach this. In fact, although a man's daily labour has a very large range, as from 300,000 foot-pounds when lifting dung into a cart to 1,500,000 foot-pounds when pushing or pulling horizontally; yet, the average is not above one million foot-pounds, as will be seen from this diagram:—

Kind of labour.	Amount of work in foot-pounds.	Authority.
Brick-layer's labourer carrying bricks	1,627,200	Mayhew.
Coal whipping	1,293,600	,,
Ascending Faulhorn	1,074,931	Wislicenus.
Do. do.	938,746	Fick.
Treadmill	1,008,000	Mayhew.
Do.	861,156	Ed. Smith.
Turning a winch	837,760	Coulomb
Pedestrians (20 miles a-day)	792,000	Haughton.
Paving and pile-driving	788,480	Coulomb.
Porters carrying loads	732,480	,,
Shot-drill punishment	694,400	Haughton.
Average	967,614	

And even when we add the calculated internal work of a man's body, as the beating of the heart and the movements of respiration, the total of it does not much exceed a million and a-half foot-pounds a-day.

External work or actual labour ...	967,614	foot-pounds.
Work of circulation (75 beats a minute)	497,880	,,
Work of respiration (15 a minute) ...	98,064	,,
Total ascertainable work per day ...	1,563,558	,,

It is evident, therefore, that a large portion of our food must escape digestion and absorption; indeed, the thermotic power of the food actually consumed daily, as estimated by the carbonic acid exhaled and the urea secreted, is not more than sufficient to raise the temperature of 10,000 lbs. of water one degree of Fahrenheit. This is equal to a force of 7,720,000 lbs. lifted a foot high; so that the ascertainable work of the food is about one-fifth of its actual energy, the rest of the power being consumed in molecular movements within the animal body. Helmholtz asserts that the external work should be a fifth part of the mechanical force of the digested food; but labour must be well applied to develop this proportion of its energy.

In the steam-engine, according to Sir William Armstrong, only a tenth part of the actual power of the fuel is realized as work. The human machine is therefore more economical of its force than a steam-engine; in fact it is assumed by Heidenham and others that not less than half of the force applied to the living muscles, as it is developed in their tissue, is utilized. But although the animal machine is so much more economical of force than the steam-engine, yet on account of the costliness of its fuel, &c., it is far more expensive. Taking, for example, a steam-engine of one-horse power (that is, a power of raising 33,000 lbs. a foot high per minute), it will require two horses in reality to do the same work for ten hours a day, or twenty-four men; and the cost will be 10d. for the steam-engine, 8s. 4d. for the two horses, and just £2 sterling for the twenty-four men.

Dr. Frankland has estimated the weight and cost of various articles of food required to be oxydised in the animal body in order to raise 140 lbs. (a rather small man) to the height of 10,000 feet, supposing that only one-fifth of the actual energy of the food is manifested as external work. Here is a part of his table:—

	Ounces required.	Cost. s.	d.
Oatmeal ...	20·5	0	3½
Flour ...	21·0	0	3¾
Pea-meal ...	21·4	0	4¼
Bread ...	37·5	0	4¾
Potatoes ...	81·1	0	5¼
Rice ...	21·5	0	5½
Beef-fat or dripping	8·9	0	5¾
Cheshire cheese	18·5	0	11½
Cabbage ...	192·3	1	0¼
Butter ...	11·1	1	0¾
Hard-boiled eggs	35·3	1	2½
Lump-sugar...	24·1	1	3
Milk ...	128·3	1	3½
Lean beef ...	56·5	3	6½
Guinness's stout	6¾ bottles.	5	7½
Bass's pale ale	9 do.	7	6

The motive power of fatty foods is thus shown to be far higher than that of lean meat or farinaceous substances, and this accords with experience, for the labouring classes have long since discovered that fat bacon is a good material for heavy work. Its efficacy may, in great part, depend on the ease and certainty with which it is digested and utilised in the body.

The *fattening functions* of food are liable to great variation, not merely from the quality of the food itself, but from the peculiarity of the individual consuming it. This is a matter of common observation, and is well-known to the breeders of stock. Messrs. Lawes and Gilbert found in their experiments on the feeding of bullocks, sheep, and pigs, that very different quantities of food were required to produce the same increase of weight. Oxen and sheep, for example, feeding on the same diet, namely, oil-cake, hay, and turnips, consume, in one case (that of oxen), 1109lbs. of dry substance for every 100lbs. of increase in the live weight, while in the other, the sheep consume only 912lbs.; and pigs fed on barley-meal will fatten to the same extent on 420lbs. of the dry material. Pigs, therefore, store up about one-fourth of their food, reckoned in this way; sheep about one-ninth, and oxen only one-eleventh.

The proportions of the several constituents of the food are also very differently used by these animals; for in every 100 parts of the dry food eaten, the several amounts of nitrogenous, carbonaceous, and mineral matters are thus disposed of:—

	Constituents of the dry food.	Proportions in dry food.	Proportions stored in animal.	Proportions in manure.	Proportions lost in respiration.
Oxen	Nitrogenous ..	19·66	0·8	29·1	57·3
	Carbonaceous ...	72·86	5·2		
	Mineral ...	7·48	0·2	7·4	—
		100·00	6·2	36·5	57·3
Sheep	Nitrogenous ...	19·41	0·8	25·1	60·1
	Carbonaceous ...	73·57	7·0		
	Mineral ...	7·02	0·2	6·8	—
		100·00	8·0	31·9	60·1
Pigs	Nitrogenous ...	12·38	1·7	14·3	65·7
	Carbonaceous ...	85·00	15·7		
	Mineral ...	2·62	0·2	2·4	—
		100·00	17·6	16·7	65·7

So that the power of appropriation is greatest with pigs and least with oxen; in fact, of every 100lbs. of the several constituents of the food, the following are the proportions stored up in the three classes of animals:—

	Pigs.	Sheep.	Oxen.
Of 100 Nitrogenous ...	13·5	4·2	4·1
Of 100 Carbonaceous ...	18·5	9·4	7·2
Of 100 Mineral ...	7·3	3·1	1·9

It will be noticed, too, that the proportions lost in respiration are very different in the three cases; for it is greatest in the pig—amounting to nearly 66 per cent. of all the food eaten, and least in the ox, 57·3 per cent. These proportions represent the vital work of the body during the processes of growth and repair.

The time also that is occupied in producing fat and muscular tissue is different with these animals, for the pig increases from 6 to 6·5 per cent. of its weight per week; the sheep not more than 1·75 per cent.; and the ox only 1 per cent. Some of this difference is, doubtless, due to the quality of the food made use of, for the pigs were fed on a nutritious and easily digestible diet—oat-meal; while the sheep and oxen made use of food with a large quantity of cellular tissue and woody fibre: and here, I may remark, that the power of utilizing the inferior varieties of food, is very different with different classes of animals. Man, as I have already explained, is unable to digest woody fibre, or even the harder kinds of cellulose; it is doubtful, indeed, whether he can digest cellulose at all. The pig, also, has but a limited capacity for this kind of work; whereas, oxen and sheep, and the herbivora generally, can eat woody tissues with advantage, and convert them into flesh and fat. In eating meat, therefore, we are utilising the digestive powers of other animals; are and in fact, employing their stomachs to do for us that which we could not do for ourselves. This, as Mr. Lawes says, is proved not merely by the testimony of common experience, but also by certain anatomical facts relating to the structure and comparative size of the stomach in different animals; in oxen, for example, the stomach weighs 51 ounces for every 100 lbs. of live weight; in sheep it weighs 39 ounces; in pigs 14 ounces; and in man only 6 ounces. It is manifest, therefore, that the food of man should be more concentrated than that of the lower animal; and that he acts wisely in eating flesh and fat, which are the very essence of food, for he thereby economises labour, and employs the assimilative powers of other creatures to bring the crudest materials into a nutritious and highly digestible form. It is true that man, in common with other animals, is able to convert starch and sugar into fat, and the lower qualities of albumen into flesh, but by so doing he expends force, for in the case of fat he locks up in it twice and a half the potential energy of starch and sugar.

Looking broadly, therefore, at the functions of food, and regarding the animal body as a machine in which potential energy is rendered active, it would appear that its main duty is to develop force by the oxydation of carbo-hydrogens contained in the blood, and not by the oxydation of tissue. A portion of tissue no doubt decays in the transference of its energies to other forms of action, and requires repair; but the decay is scarcely more rapid at one time than another, and is, in no case, when sufficient food is supplied, the cause of mechanical labour. "In man," says Dr. Frankland, "the chief materials for muscular power are non-nitrogenous; but nitrogenous matter can also be employed for the same purpose, and hence the greatly increased evolution of nitrogen under the influence of a flesh diet, even with no increase of muscular exertion. The non-nitrogenous matters, also, which find their way into the blood, yield up all their *potential* energy as *actual* energy; whereas the nitrogenous in leaving the body as urea carry with them a portion (at least one-seventh) of their potential energy unexpended. The transference of potential energy into muscular power is necessarily accompanied by the production of heat within the body, even when the muscular power is exerted externally. This is, doubtless, the chief, and probably the only source of animal heat."

LECTURES ON VENEREAL DISEASES

DELIVERED IN

DR. STEEVENS' HOSPITAL.

LECTURE III.

By ROBERT McDONNELL, M.D., F.R.S.,

ONE OF THE SURGEONS TO STEEVENS' HOSPITAL.

GENTLEMEN,—If you will allow me, I shall commence to-day's lecture by an anecdote: the case alluded to is one which illustrates remarkably well many of the phases connected with the evolution of syphilis, to which I wish to direct your attention.

About two years ago, upon entering my own house, I was informed that there was a person waiting to see me. I found an individual with whose appearance I was quite familiar, although his name had escaped me. For the moment I did not doubt that he had been one of my former pupils, who had undergone that remarkable metamorphosis, which the medical student undergoes after having been in the military or naval service, or abroad in our colonies for some years; than which the transformation of the tadpole into a frog, or a catterpillar into a butterfly, is hardly more remarkable. I shook hands with him in a friendly way, and taking him by the arm, begged of him to walk into my study along with me. I observed that there was something stiff and formal in his manner, as he said to me—"Sir, I have called on you to thank

you for your kindness to me." I said, interrupting him, "Come along with me into my study;" as we entered the room, he repeated, "I have taken the liberty of calling upon you to thank you for your kindness to me some years ago, when I was *an inmate of the Mountjoy Convict Prison.*" You can easily suppose that I was rather surprised to find myself on such friendly terms with such a person. "Oh! indeed," I said, somewhat taken aback, and almost instinctively retreating a step or two—"Yes, yes, I now remember perfectly all about the circumstances of your case. Where have you been lately?" I asked with come confusion. He informed me that some weeks before, he had got his discharge from the Convict Prison on Spike Island, on the expiration of his sentence.

Let me now turn, gentlemen, to this man's case, as noted by me some years before. In 1857, A. B. came under my observation in the Mountjoy Convict Prison. He at that time had a chancre on the prepuce with marked induration. I learned that it had not appeared until some days after his committal to prison, and that at the time when I saw it there had been no treatment of any kind. This was on the fourth day after he had noticed the sore. He had congenital phymosis; on the following morning I performed circumcision, removing the sore entirely. At this time I could not discover anything more than a very trifling glandular enlargement in the left groin. The wound healed kindly, but as it healed a constellation of glands appeared in each groin. Fifty-two days after the operation he came before me, suffering, as he thought, from a severe cold; the skin was hot, pulse quick, he complained of general lassitude and mental depression, with headache and pain in the back. He was ordered diaphoretics and warm baths. Four days later a roseolar eruption declared itself, mucous tubercles appeared in the throat and fauces, and he was disturbed at night by rheumatic pains. The eruption came out chiefly upon the chest, and abdomen, and slightly on the arms; the glands in the neck became enlarged, but not to a very considerable extent. He was treated with sarsaparilla, senna, Dover's powder at night, warm baths and iodine. The eruption disappeared in three weeks. At the end of 52 days from the appearance of the first eruption, a second crop made its appearance—this time papular in form, intermixed with pustules. This eruption was remarkably symmetrical in character, and occurred on the face, shoulders, back of the arms, and fore-arms, very slightly on the trunk, thickly on the outside of the thighs and legs. The throat was very sore, the right tonsil ulcerated. This disappeared also, yielding to non-specific treatment. His hair fell out, and although the eruption on the scalp was very slightly marked, the engorgement of the glands in the neck was more considerable than at first. Three months from the appearance of this second eruption, and while the copper-coloured stains were still to be remarked on the surface of the body, a third and slighter crop of the papular kind made its appearance upon the same parts of the body. This, likewise, yielded readily to a non-specific treatment. Five weeks later a fourth crop, of a still milder kind, appeared over the same parts; no glands suppurated, no iritis supervened. He regained his health, and at the end of twelve months passed from under my notice to reappear in the manner I have described, after a lapse of eight years. I naturally inquired whether he had had any further symptoms referable to venereal disease. He told me "no," that he had been in the enjoyment of very good health, and he repeated to me, in a very respectful manner, that as he was about to leave this country, he had taken the liberty of calling upon me to thank me for my attention to him, before he started for America, where he intended to commence a new life. Now, gentlemen, by an accident I have been able to follow this case even further. This individual has since married, and is now the father, I am assured, of a perfectly healthy child, six months old. We have here a typical case in which chancre was destroyed at a very early period, yet constitutional syphilis followed, ushered in after a time by the usual prodromata, presenting most of the characters of a well-marked case of rather severe syphilis, and recurring in the eruptive form four times; yet, as far as we can judge, undergoing a complete cure without any mercurial treatment whatever. It would be quite useless for me to enter into any detail of all the other cases which, under similar circumstances, I have seen undergoing cure without specific treatment, where I was absolutely certain that there could not be present any disturbing influences. In the treatment of ordinary patients, it is, I assure you, very difficult to be quite certain that directions are fully carried out. I recollect myself pointing out with considerable satisfaction, a case of syphilis which was cured, as I supposed, without the administration of mercury; yet I afterwards found that this individual, who was an hospital patient, had taken a share of the mercurial pills ordered for another person. On the other hand, Diday gives an amusing case in which he himself having prescribed mercurial treatment, discovered, long afterwards, the boxes of pills untouched in the drawer of his patient's dressing-table; yet his patient was cured, and, as he says, remained cured for more than nine years without any mercurial treatment.

In a prison conducted on what is known as the "cellular system" no such sources of error can exist. We have perfect scientific precision in watching our cases.

The following is the description given in the report of the Venereal Committee of constitutional effects of syphilis:—

"The constitutional manifestations of syphilis follow the primary sore at an uncertain interval of time, ranging from four to ten weeks; the average term being about six weeks. Its first indication consists in a sense of chilliness, followed by heat of skin, accelerated pulse, general lassitude and mental depression. These symptoms are accompanied by pains in the limbs, and especially in the joints, often of a severe rheumatic character. In the course of two days or more the skin upon the chest, back, abdomen, and arms, occasionally in severe cases over the whole surface of the body, exhibits, on examination, some form of eruption, most commonly of an erythematous or roseolar character of a pale pink colour. Such eruption terminates in copper-coloured patches.

"If the disease be severe, well-developed papules, vesicles, and pustules may appear over the back and head, intermingled with, or following the rash. The pulse continues frequent. The throat exhibits a florid discolouration, which involves the tonsils and the neighbouring parts of the soft palate. Of the condition of the throat, the subject may remain for a time unconscious. This stage of the disease, which continues for some days stationary, may be preceded, accompanied, or succeeded by enlargement of the inguinal and posterior cervical glands. The latter, however, are not always affected. These indications are accompanied by impaired health, and by loss of physical strength.

"A sense of general debility prevails, coupled with pallor of the skin, the blood being said to be deprived of a portion of its red corpuscles. The tonsils ulcerate, and exhibit either an excavated ulcer, or a plain flat surface, of a soft red flabby aspect. The hair falls off (alopecia). On the side of the tongue at a yet later date, and generally on its under surface, are formed small white ulcers, three or four in number, of about the size of a split-pea, which, on healing, leave a white and somewhat depressed cicatrix, while others appear on the soft palate and roof of the mouth, on the gums, or at the angle formed by the two jaws. Condylomata, soft mucous-like ulcerations at the angles of the mouth, nostrils, nates, and female genital organs, iritis, with its complications, and onychia frequently occur. Such are the various symptoms that mark the progress of syphilis in the majority of cases, and which may be said to belong to the acute form of the disease. There is, however, another group of symptoms not preceded by febrile derangement, and more chronic in character. To this belong psoriasis, lepra, and tubercular eruptions, honey-comb eruption of the palms of the hands, the excavated

ulcer of the tonsils, and enlargement of the testicle. All these affections are in a remarkable degree almost destitute of pain."

In severe cases these symptoms succeed each other, wave after wave, eruption after eruption, for four, five, or six outbursts, with intervening periods of bitterness. In mild cases, one, two, or perhaps three crops of slight eruptions end the affair.

That syphilis presents itself to the practitioner in forms which vary greatly in severity, that common sense and reason indicate that the treatment should vary with the severity of the complaint, these are the simple principles which I must now ask you to bear in mind. The greatest of all practical questions with reference to this formidable complaint appears to me to be—how are we to discriminate the one class from the other—how are we to separate the cases of benign from those of malignant syphilis? You may justly say to me—"You have already said that it is not possible, with anything like certainty, to diagnose the simple from the syphilitic venereal sore; to say of one sore that it will be the forerunner of constitutional syphilis—of another that it will not. You admit that this is a matter of difficulty, if not impossibility. How, then, can you hope to tell in advance whether the constitutional disease which will succeed the syphilitic sore may turn out to be mild or severe." Let me say, in reply, that you must wait patiently and watch carefully. As the gradual evolution of the complaint goes forward, you will perceive certain indications, certain circumstances with regard to your patient's age, habits, constitution, &c., which will indicate to you with considerable precision, the course the complaint is going to run, and you must adapt your treatment accordingly. But you say again—"Are we to wait and watch, looking quietly on at the evolution of this formidable malady—are we not rather to attack it at once, and by mercurial treatment in the beginning to prevent constitutional disease." Gentlemen, let us be candid. We cannot prevent the constitutional disease. On this subject the evidence brought before the Venereal Committee exhibits a marvellous unanimity. The report says:—"No treatment by mercury, whether moderately or freely administered for this purpose, can give exemption from the liability to constitutional disease." It is true that a few of the persons examined before the Venereal Committee adhered to the opinion which was so confidently put forward by the last generation of practitioners—viz., that constitutional syphilis is prevented by the mercurial treatment of the primary disease; but the error of our ancestors is easily explained. They treated all ulcers on the genitals with mercury; four out of five of these were simple sores; in four out of five no secondary disease followed or ever would have followed under any treatment, and they attributed to mercurial treatment what was in reality due to the non-infecting character of the simple sore. If, therefore, you fully recognise the fact that you cannot prevent constitutional syphilis from coming on, you will have less scruple in calmly watching the evolution of the disease, and you will be more reconciled to the issue when you know that this is the surest mode of obtaining the evidence—the all-important evidence—on which your prognosis and your treatment are to be based. I have already told you in a former lecture that Diday speaks of eight distinct and successive features which mark the progress of every syphilitic case.

1st. The contaminating cause. We have comparatively little opportunity in this country for investigating it. The method of confrontation as it has been called, the tracing home of the syphilitic affection to its source in the female, the confronting in fact of the sore on the male genitals with that of the parent sore from which it takes its origin, has borne good fruit, and been one of the most decisive methods of proving the duality of the venereal poison. Owing, however, to the uncontrolled condition of prostitution in this country, we have but rare opportunities of doing it, and for practical purposes we may set aside any evidence which we are likely to derive from this source.

2nd. The first incubation—that is to say, the period which elapses from the time of the impure contact until the moment when the sore becomes apparent, is a point upon which we can sometimes obtain precise information, and when we can, information of great importance. It may be laid down as a general rule that the longer the period of incubation, the less virulent the infection. We have already seen that considerable difference of opinion exists with reference to the duration of this period of the first incubation. In ten cases of inoculation from secondary lesions the mean incubation has been 28 days; in two cases of inoculation from primitive lesions the mean incubation has been 18 days; while Diday assigns 14 days as the mean period for incubation in the ordinary run of cases. As in gonorrhœa, so in syphilis, the longer the period of incubation the less virulent, in all probability, the nature of the virus; but in truth we cannot build much upon this with reference to our prognosis.

3rd. The primitive lesion, that is to say the chancre, and its characters have been thoroughly studied and appear to afford some important testimony. The initial lesions, unattended with much induration, may be stated, as a rule, to be the forerunners of the milder form of syphilis. The unindurated syphilitic chancres which have been described by various writers under so many names (the venerola vulgaris, the chancrous erosion, the condylomatous affection, the superficial erosion, patchy excoriation, superficial primary syphilis, the chancriform erosion), appear from the statistics of Bassereau generally to give rise to mild syphilis. Thus, from his tables, we find:—Of 170 cases of roseolar eruptions the primitive lesion was in 146 of them an erosion; in 24 of them a hard chancre.

4th. The period of the second incubation. The duration of this period has not been accurately fixed as yet—that is to say, the period over which it extends. Some authors date it from the time of the impure contact to the time when the secondary lesions declare themselves. Others date it from the day upon which the chancre is observed up to the period when those constitutional symptoms present themselves, which are about to usher in what we call the secondary lesions. The latter is probably the best definition, and can, generally speaking, be accurately defined, as we can almost always find out from the patient when it was that the sore was first noticed, and we can invariably discover the time at which the malaise and general discomfort supervenes, which is the sure indication that the constitutional symptoms are about to make their appearance. It is a remarkable fact that this period is rather longer in cases of severe syphilis, while the milder forms generally develop themselves more rapidly. Diday gives forty-seven days as the average period of the second incubation for cases of "verole faible," fifty-three days as the average period in cases of "verole forte." The mild roseolar eruption appears early, the severer forms of eruption appear later. In determining, therefore, the severity of the cases, the length of the period of the second incubation affords valuable evidence.

5th. The prodromata. Under this head are placed the anomalous symptoms which usher in the first outbreak of constitutional symptoms—headache, rheumatic pains, or, as they are called, osteocopic (ὀστεον a bone, and κοπος, fatigue, bone-ache), syphilitic chlorosis, depression of spirits, tendency to rigor and general discomfort. It is quite certain that, as in many other eruptive affections, these general symptoms may sometimes be very aggravated, and yet the parturient mountain gave birth but to a mouse. Severe prodromata are by no means necessarily the forerunners of severe syphilis.

6th. The first outbreak of constitutional symptoms is, as Diday expresses it, the true touchstone of the intensity of the syphilitic infection. This outbreak shows itself in the mucous membranes or the external integument, very generally first upon the scalp in the form of the corona veneris. Fortunately, the benign forms are the most frequent. More than one-half are of the roseolar variety,

something like 25 per cent. belong to the papular, while the scaly, vesicular, and pustular are of much rarer occurrence. These syphilitic eruptions or syphilides, as they are called, are after all most important indications of the severity of the syphilitic intoxication. I believe it is rarely necessary to have recourse to specific treatment for the roseolar form of the disease, very rarely indeed in persons under thirty years of age, and I should venture to say never when we find that the second crop of eruption which may follow some weeks later is not of a severer kind than the first.

7th. The glandular affections, technically called adenopathia. To this group belong the glandular affections, which appear in the lymphatic glands throughout the body, first in the groin, afterwards in the neck, sometimes in the axilla.

These, generally speaking, have little tendency to suppurate unless called into action by some cause which may be regarded as extra syphilitic, as a scrofulous diathesis, the occurrence of erisypelas, or local irritation of some kind. In the milder cases these glandular engorgements gradually become dissipated. When they suppurate from local causes, they form a very troublesome complication, and frequently necessitate a specific treatment.

(To be continued.)

Original Communication.

ON THE OPERATION FOR STRABISMUS AND ITS AFTER TREATMENT.

By J. G. HILDIGE, F.R.C.S.I.

NOTWITHSTANDING the almost mathematical accuracy with which the operation for strabismus has been treated of by German and English surgeons, it occasionally happens, no matter how carefully the operation may have been performed, that the degree of parallelism resulting from it is far from satisfactory, the eye either returning to its former position or tending to wander in the opposite direction. A secondary operation[1] is just as liable to be attended with similar results, besides being in no small degree irksome to both patient and surgeon. Having experienced this in my own practice I have long been anxious to discover a means of obviating it, and I now propose to describe, as briefly as possible, a mode of treatment which has lately suggested itself to me, and which I have found to be attended with most excellent results. It consists in drawing with an extremely fine point of nitrate of silver perpendicular lines of about one-fourth of an inch in length between the angle of the eye and the margin of the cornea, on the side of the eyeball opposite to that towards which the eye tends to wander. For instance, if the internal rectus be the muscle which has been detached (strabismus convergens), and if the eye some time after the operation shows a disposition to return to its former position, I draw the lines, two at the utmost on the conjunctiva, between the external angle of the eye, and the margin of the cornea ; on the other hand, if the eye wanders too much outwards after the detachment of the muscle and does not become parallel with the other eye after the expiration of the period allowed for the subsequent contraction of the wound, the lines are drawn on the nasal side of the eyeball, and in the same position as on the opposite side.

In order to explain more fully this mode of treatment I shall give the details of one or two cases to which it has been applied with the best possible result.

Case 1.—Miss de M——, æt. 10, of Kilkenny, was operated on by me for strabismus comergens in the month of May, 1866. The affection had come on shortly after birth ; the child's mother, however, did not remember the exact period when it was first observed. The right eye was turned inwards to the extent of about two lines, and its vision had become impaired from disuse. I operated on both eyes at the same time, detaching the muscles to such an extent as to allow about one-quarter of a line for the subsequent contraction of the wound. At the end of a week the left eye had become nearly straight, but the right one had become more divergent, so as to form an external strabismus of about one line and a-half.

As there was now little or no probability of the contraction of the wound acting to any extent on the position of the eye-ball, I determined to make a trial of the nitrate of silver. I drew one or two lines with an extremely fine point of nitrate of silver, midway between the internal angle of the right eye and the margin of the cornea, and directed the patient to be kept in a darkened room, with cold applications to the eye. On the following day there was a marked improvement in the position of the eye, and it was only necessary to repeat once more the application of the caustic, when the eyes became perfectly parallel, and remained so. I saw this young lady about four months afterwards, when, to use her mother's words, no person would have known she had ever squinted.

Case 2.—Miss H., æt. 12, of Rathgar, was operated on for strabismus convergens on the 22nd of May, 1867. Her eyes became parallel about ten days after the operation, and shortly afterwards she was allowed to return to her daily avocation.

Three weeks elapsed before she again presented herself, when I found, on examining her, that her left eye had returned to very nearly the same position as it had occupied previous to the operation—that is to say, turned inwards to the extent of about one line and a half. She stated that she had been using her eyes pretty freely since I had seen her, and that her left eye had gradually commenced to squint again. I drew one line between the external angle of the eye and the margin of the cornea, and gave her the usual directions to abstain from using it, and to remain as much as possible in a darkened room for a few days. At the end of two days the eye had altered its position to the extent of one line, and, as well as I remember, it was not necessary to use the caustic a second time, as the eye became perfectly parallel, and remains so to this day.

I have treated other cases of failure of the operation for strabismus by this method, and my experience of it has convinced me that if it be resorted to within a short period after the operation, and if there be no incongruence of the retina present, it is almost certain (humanly speaking) to be attended with success. With regard to its mode of action, I am disposed to think that it is not wholly mechanical ; in fact, that the psychical element, as it is denominated by our German brethren, is brought more or less into play ; be that as it may, it has the advantage of being a simple and—according to my experience—a most effectual remedy, and unattended with any risk whatsoever.

[1] I include the different kinds of conjunctival sutures under this head.

Hospital Report.

MEATH HOSPITAL AND COUNTY OF DUBLIN INFIRMARY.

Cases under the care of Mr. PORTER.

A LARGE ULCER OF THE ARM, CAUSED BY A BURN: AMPUTATION.

WE visited the Meath Hospital on Monday, the 9th inst., where, through the kindness of Mr. Porter, we were present at an amputation of the arm performed by him. The patient, a female aged fifty-six years, had, seventeen months previously, been burned by falling against a grate whilst baking bread. The burn extended from a point three inches above the left wrist, to two inches above the elbow-joint, and had destroyed the skin and areolar tissue. A large, weak, flabby ulcer resulted, but this had, under treatment, healed to the extent of leaving an ulcerated sur-

face three inches below, and one inch and a half above the joint, every aspect of the articulation being in a state of ulceration. She suffered intense pain, and lost her rest. The sore discharged profusely, and she was greatly emaciated by nocturnal perspirations, and occasional attacks of diarrhœa. The obstinate nature of the ulcer, and the rapid failing of the woman's strength made Mr. Porter decide upon removing the source of irritation. The patient having been thoroughly placed under the influence of chloroform, and the axillary artery having been compressed by a colleague, Mr. Porter cut an anterior and posterior flap by transfixing the arm about one inch above its centre. He then rapidly carried the knife round the bone, and immediately sawed it through. The severing of the limb was completed in sixty seconds. Mr. Porter secured all the vessels by ligature, and a very neat stump resulted when the flaps were brought together by silver wire sutures. Mr. Porter remarked to the class, that the patient on whom he had operated gave them a forcible example of a *remote* source of danger from a severe burn. She had escaped from shock, irritative fever, hæmorrhage, tetanus, and was then sinking quickly from hectic. He pointed out the advantage of amputation in this case, as giving the patient the best chance by removing the cause of the wasting fever from which she was failing.

LIPOMA TESTIS: "SYME'S OPERATION."

We also saw a very interesting case of lipoma of the left testis, on which Mr. Porter had operated. The patient, aged twenty-eight years, had been admitted under Mr. Porter's care, suffering from a fungus growth the size of a small hen's egg, protruding through the left side of his scrotum. The case displayed all the characteristic signs of lipoma, without any of those attendant upon malignant disease. The man imagined that it had arisen from an injury to the left testicle, inflicted by a trochar during the operation of tapping a hydrocele. Mr. Porter pared the edges of the aperture in the scrotum through which the unravelled structure of the testis had protruded. He then forced the testicle back, and brought the pared edges together with three pins, and twisted sutures. Mr. Porter pointed out the excellence of Mr. Syme's operation in these cases, by which the gland is saved, instead of the former practice of shaving off, or burning down the fungus with caustics. He also described the leading features in the diagnosis between this affection and malignant disease of the testicle.

FIBROID PHTHISIS.

THIS subject was brought forward at the Clinical Society of London by Dr. Andrew Clark, who read the following case:—

General Summary.—A woman, æt. 28, four years married, childless, sprung from healthy parents, said to have been temperate, and to have enjoyed good health till three years before, when she had ascites, from which she recovered in eleven months, began, in July, 1867, to suffer from vomiting, prostration, cough, occasional hæmoptysis, muco-purulent expectoration, containing lung tissue, œdema of extremities, and intermitting diarrhœa, and becoming rapidly worse, died comatose on the 5th December of same year. Post-mortem examination revealed, as had been predicted during life, fibroid disease of left lung, with dilated bronchi, cheesy deposits, and cavities arising from their disintegration; enlargement (and waxy degeneration) of liver; granular contraction (and some waxy change) of kidneys; ulceration of the bowels; enlargement of mesenteric glands; and fibroid degeneration of, or deposit in, other organs and tissues.

State on Admission.—Patient greatly emaciated, reclines on her back, and takes little notice. Pupils dilated and sluggish. Is drowsy, but sleepless. Answers questions with difficulty, but as it seems correctly.

Teg. Org.—Skin dusky, yellowish, dry, rough; white patches here and there. Hair dark, scanty, coarse. Fingers clubbed. Temp. in axilla 97·4.

Dig. Org.—Teeth decayed, yellow: sordes. Tongue dry, red, and cracked; thirst, vomiting; flatulence; diarrhœa, preceded by griping pains. Hepatic dulness, greatly increased downwards and to left. No increase of splenic dulness.

Genito-urin. Org.—Menstruated two months ago. Slight leucorrhœa. Urine deficient in quantity, pale, acid, of a density of 1012, and containing a tenth of its bulk of albumen. Scanty deposit, exhibiting granular matter and small hyaline casts.

Resp. Org.—On account of weakness of patient, front and lateral parts of chest alone examined. Respirations 20 per minute, and chiefly abdominal.

Examin. of Left Side.—Front depressed and movement slight. Supra-clavicular region percussion tympanitic; breath sounds blowing: resonance broncophonic, with echo. From second to fifth rib, and from near sternum to posterior part of axillary region, hard resistant dulness, with considerable retraction of chest-wall. In front of this region, inspiration bronchial, and accompanied by moist subcrepitant râles; expiration dry, and not sensibly prolonged. In axillary region breath sounds tubular, and partly masked by coarse crepitation; vocal resonance broncophonic. At two spots breathing cavernous and voice pectoriloquous; here metallic click is heard coincident with heart's contractions. Along posterior axillary line an occasional creaking-leather sound is heard and vocal fremitus and vocal resonance are notably diminished. Over lower part of lung, inspiratory murmur harsh; and expiratory murmur, which in its first half is blowing, terminates only after apparent cessation of movements of thoracic walls by a few gentle puffs. A fine dry crepitation is developed by forced inspiration. Ultimately in this region there were uniform dulness, tubular breathing, and broncophony.

Examin. of Right Lung.—Percussion over anterior third tympanitic; elsewhere normal. Inspiratory murmur harsh and divided; expiratory prolonged, blowing, and accompanied by sibilant ronchi; vocal resonance increased.

No distress of breathing. Cough infrequent, but paroxysmal, and ending in vomiting. Expectoration occurs at close of paroxysms. Sputum mucopurulent, streaked with pigment, and not lumpy. Bands and areolæ of elastic tissue present.

Circ. Org.—Apex beat at upper border of fourth rib, just outside nipple. Visible pulsatile movement (nearly synchronous, with ventricular contraction) in second intercostal space an inch and a half from left border of sternum. Low pitched systolic murmur at cartilage of second left rib; can be followed a little way upwards and outwards, but not downwards or to right side; it is increased by deep inspiration, and modified by position. Pulse 74, small.

Nervous System.—Attention introverted. Drowsy, but sleepless. Answers when roused. Sight and hearing defective. No headache. Occasional sensations of numbness in the limbs, and tremblings. Slight œdema of feet.

Diagnosis at bedside, as in summary.

Progress of Case.—Patient varied little. Sometimes obstinate vomiting: sometimes constipation, alternating with diarrhœa. No evening fever. Pulse never rose above 92, respiration above 26, temperature above 99; till near the close of life the figures were considerably lower. Upon great restlessness followed increasing weakness; then coma; and on the 3rd December, death.

Summary of Post-mortem Examination.—Heart small, and displaced upwards; no valvular disease; origin of vessels compressed by solidified lung, with pericardium adherent to it. Right lung, with the exception of some vesicular emphysema and some thickening and congestion of the bronchial mucous membrane, absolutely free from disease. Left lung universally adherent, diminished in bulk, and about its middle third dense and fibrous. When cut open, the summit was seen to be free from disease. The inferior part was traversed by fibrous septa, some of which, pursuing a horizontal direction, occupied the place of the bronchi and blood-vessels—some, intersecting, occupied the place of the interlobular areolar tissue. Imprisoned portions of lung contained cheesy deposits, at parts broken up into cavities. Several bronchial tubes were dilated, and terminated in ulcerous dilatations. No grey granulation anywhere to be found. Bronchial glands enlarged and cheesy. Liver very large and waxy. Capsule of spleen much thickened. Kidneys granular and capsule adherent. All these organs at scattered spots became reddish-brown on the application of iodine; *so also did some minute portions of the fibroid deposit in lung.* Numerous deposits in and ulcerations of ileum. Mesenteric glands enlarged.

Extracts from Report of Microscopic Examination.—Lungs: The horizontal septa consisted almost exclusively of obliterated blood-vessels, or bronchi thickened by adventitious fibroid tissue. The intersecting fibrous bands occupying the interlobular fissures, and ramifying in varying directions from them

consisted of a true areolar tissue. In the dense slate-coloured portions of lung the alveoli were filled by what seemed an amorphous substance, having occasionally an appearance of fibrillation. At some parts this substance, under the action of weak acid or alkaline solutions, exhibited the presence of a few epithelial-like cells; at others, no manipulation and no reagent revealed the presence of any structural element. It seemed as if three morbid processes had been at work—the spread of a true areolar tissue from the pleura, interlobular fissures, bronchi, and blood-vessels; the production of a fluid which pervaded the textures, and clotted into amorphous moulds of the alveoli; and a simple fibroid degeneration of normal textures.

The smaller cheesy masses occupying the centres of the lobules were composed chiefly of flattened epithelial-like cells, with particles like the white blood corpuscles, a few blood-discs, and some granular matter. The larger cheesy masses were differently constituted. In each the central parts were composed of a granular detritus; outside lay free nuclei and granular matter; still more externally were disintegrating cells; and on the circumference were swollen and distorted cells, with multiple nuclei and vacuoles. To the naked eye the masses had the aspect of what is called cheesy tubercular infiltration; but the microscope showed that they had the structural characters of what the author has described as *epithelial pneumonia*.—LECTURES AT COLLEGE OF PHYSICIANS, 1866.

. . . . . .

Remarks.—It is no longer matter of doubt that the term phthisis, as commonly employed, comprehends several states of lung, distinct in their origin, nature, progress, and issues. To set forth in a clear manner the assemblage of symptoms by which they are respectively to be distinguished during life is the greatest desideratum in the pathology of lung affections. Without such knowledge the results of clinical inquiry are vitiated, and the conclusions drawn from therapeutical experiments rendered worse than worthless. . . .

The term fibroid phthisis is applied to those cases in which the leading anatomical facts are the absence of tubercles in the lung, and its invasion and contraction by fibrous tissue, or a fibrogenous substance involving bronchial dilatations, cheesy deposits, and small cavities commonly confined to the lower two-thirds of the organ. . . .

The diagnosis in this case was not difficult. Tubercle was excluded by the absence of disease in right lung, by the assumption that the apex of left lung was free, and by the negative character of the general symptoms. There was no great hurry of the circulation, no distressing dyspnœa, or breathlessness, no evening fever, no continued elevation of temperature (Ringer), and no profuse perspirations. In the presence of positive signs of another constitutional affection, the occurrence of diarrhœa cast no serious doubt upon the propriety of the exclusion. Diarrhœa, dependent or not upon ulceration of the bowels, may arise in almost any form of chronic disease to which the lung is liable. Cirrhosis and chronic pleurisy were excluded by the evidences of pulmonary cavities derived from the physical signs, and from the microscopic examination of the sputum. Was it cancer? The patient's aspect, the rapid progress of the disease, its unilateral character, the retraction of the chest-wall, the continuity and extent of the dulness, and the frequent hæmoptysis, all disposed one to the adoption of this conclusion. But then the very considerable contraction of the chest-wall, the moist râles, the characters of the sputum, the justifiable conviction of the presence of several scattered cavities, the absence of any evidences of outgrowth, enlarged glands, or tumours in other parts, and, above all, the presence of many concurrent evidences of constitutional fibroid degeneration, eliminated the idea of cancer, and led to the only conclusion tenable, that the case was one of *Fibroid Phthisis*.

The evident existence of fibroid degeneration in various organs and tissues led to the conclusion that the lung disease was essentially constitutional; and the fact of the disease being unilateral was held, in the light of the history of primitive pulmonary cancer, to be no bar to this conclusion.

The existence of cheesy deposits was inferred, first, from the physical signs—a coarse, rather dry crepitation, followed by dulness, tubular breathing, and broncophony; secondly, from past pathological experience of such cases; and, thirdly, from the existence of ulcerations in the bowels. Cheesy matter—that is, almost any pathological product in the way of structural and chemical degradation—appears from the author's experiments, often repeated, to be in some manner an efficient cause of secondary deposits in various textures and organs, and of secondary deposits and ulcerations in the bowels.

The systolic basic bruit was inferred to be dynamic, and to be owing partly to pressure, and partly to the altered axial relation of the heart and great vessels, by reason of its variability and the readiness with which it was influenced by changes of position, by forced inspiration, and by coughing.

The case concludes with a summary of the more important circumstances tending to elucidate the nature and facilitate the diagnosis of Fibroid Phthisis.

1. Fibroid Phthisis may have a constitutional or a local origin. (C. J. B. Williams; Handfield Jones.)

2. When the disease has a constitutional origin, the fact will be indicated by the presence of signs of fibroid disease in other organs and tissues; by white skin spots (H. G. Sutton); by corneal degenerations (Canton); by anæmic urine containing granular matter, granular casts, or albumen; by evidences of cirrhotic or amyloid liver, of enlargement and hardening of spleen, and of induration of the nervous centres.

3. The constitutional state of which these growths, deposits, or degenerations are the manifestations seems to be closely connected with, if not dependent upon, the abuse of alcohol (Huss), syphilis (Wilks), rheumatism and gout (Author), exhausting discharges (Dickinson), and defective excretion (Author).

4. The actual product of this state appears either as a true fibroid tissue or as a tough, hard amorphous fibrogenous substance (Williams; Walshe). The latter is closely akin to the "amyloid material," and even in the lung is sometimes reddened by iodine. It does not appear to be the product of cell proliferation, but to be the result of a real exudation in the ordinary sense of that term. The former can always be traced into continuity with perilobular, peribronchial, perivascular, or subpleural areolar tissue. The latter occupies the alveoli, and is often found in isolated patches. Structural elements, such as are seen in adjacent parts, are often found in it. When nuclei are present in it, they are the ordinary circular nuclei of the alveolar walls, and not the spindle-shaped or oat-like nuclei of connective tissue. In other organs, the fibrogenous material sometimes contains oat-shaped nuclei derived from proliferation of the vascular walls. To this source also are to be referred many of the nuclear fibres and spindle-shaped cells supposed to be illustrations of the cellular development of fibrous tissue.

5. When the disease is not of constitutional origin, there will be found evidence either of the pursuit of some occupation exposing the patient to the inhalation of irritating particles (Peacock; Greenhow), of the existence of tubercular phthisis, long continued bronchitis, or of some former attack of acute disease, such as fibrinous pleurisy, pericarditis, or what the author has called the corpuscular form of pneumonia.

6. The disease commonly affects one lung, and more commonly the left than the right.

7. If the disease affects both lungs, it is, as a rule, either the effect of mechanical irritation, or it is accompanied and has probably been caused by the presence of tubercles.

In rare cases, the double affection may be caused by rheumatism or syphilis (Wilks).

8. In Fibroid Phthisis there is always contraction of the chest-wall. The percussion dulness is harder, higher-pitched, and more uniformly continuous than in any other lung disease. Resistance of thoracic parietes is greatly increased. Intercostal spaces are depressed. Sometimes the dulness is tubular. Vocal fremitus is at one time increased, at another greatly diminished. Over the fibroid lung one hears blowing breath sounds often without audible prolongation of expiration; occasionally coarse dry and moist râles, superficial creaking, and diffuse broncophony. Over cheesy deposits of any extent the breath sounds are sharply tubular, the expiration prolonged and the vocal resonance broncophonic, sniffling, and circumscribed.

9. If the apex of the diseased lung is involved in the solidification, there is reason to suspect the existence of tubercles; if there is moist crackling in the supraspenous fossa, the suspicion amounts to probability; and if with the slightest dulness over the summit of the opposite lung there is any moist crepitation, doubt is practically no longer possible.

10. When the lung below the solidification is healthy, expiration is peculiarly prolonged and puffy.

11. When cavities exist, they commonly occupy the mammary region; occasionally they are found in the base, and with extreme rarity in the summit of the lung. (Sutton's cases appear to have been complicated with tubercles).

12. When about the middle of the lung several cavities lie

near together in a horizontal or diagonal line, and are bounded by solidified lung, they are in all probability due to dilated bronchi. Cavities resulting from the breaking up of cheesy deposits are commonly isolated, irregularly placed, larger, and yield on auscultation unmistakable cavernous or amphoric breathing and pectoriloquy. The only certain evidence, however, of the existence of cheesy cavities is the presence of areolæ of elastic tissue in the sputum.

13. In the neighbourhood of the solidified lung it is not uncommon to find patches and tracts of lung in a condition of extreme vesicular emphysema; *and the atrophic changes constituting it appear in many instances to be due to plugging, or some other obliteration of branches of the pulmonary artery. It is therefore a statical as opposed to a dynamical emphysema.*

14. When the left lung is affected, the heart is usually displaced upwards, and a little outwards. When the right lung is affected, the heart is drawn chiefly outwards, and a little upwards. In both cases, a low-pitched systolic bruit is commonly heard over the pulmonary artery.

15. The cough is paroxysmal, and ordinarily induces vomiting. The expectoration varies; it is usually yellowish, greenish, or ashen grey, studded with pigment streaked with blood; sometimes fœtid, and ejected with difficulty after several ineffectual fits of exhaustive coughing.

16. The general symptoms, viewed collectively, are strikingly different from those of tubercular phthisis. The skin is, local sweats excepted, dry and inactive; there is no continuous elevation of temperature, no evening fever, seldom any hectic flushing. Till the disease is far advanced, the breathing is quiet, and the pulse below 84.

17. Slight œdema of the lower extremities is very common in the course of this disease, and almost always present at its close.

18. Patients who have long suffered from Fibroid Phthisis, whether of local or constitutional origin, become at last pallid, waxy-looking, and cachectic.

19. The disease is commonly slow in its progress, and when it complicates tubercles it retards disintegration and greatly prolongs life. This may explain some of the cases of unusually prolonged phthisis in spirit drinkers.

20. The frequent occurrence of even copious hæmoptysis, and the setting in of diarrhœa in the course of this disease, may justify a suspicion of the development of tubercles, but are not conclusive evidences of their presence. Hæmoptysis, diarrhœa, and ulceration of the bowels often occur during life without a solitary tubercle being found after death.

An animated and very interesting discussion upon the above paper occupied almost the whole evening of the 28th. The debate begun by Dr. Williams was concluded by Dr. Pollock, who alone took any serious objection to the author's views. It is not our intention to follow the various speakers in the statement of their experiences; but we must take some notice of Dr. Pollock's objections, and of the answers which were made to them. Setting aside the objections obviously arising out of an imperfect acquaintance with the author's statements, Dr. Pollock's remarks may be summarized into an assertion of the tubercular character of the disease described; the expression of his conviction that tubercles would have appeared in the right lung if the patient had lived long enough, and his opinion that cases of the kind described by the author possessed no peculiarities sufficient to justify their separation from tubercular phthisis by a distinct name.
